That this affecting appeal should be somewhat too querulous and gloomy, will not excite the wonder of those who are aware that its author, though endowed with a powerful mind, was liable to frequent fits of despondency and extreme depression of spirits; in consequence of which, the natural evils of his situation occasionally presented themselves to his imagination, in too aggravated and distorted a form. For this, he seems anxious to apologise; when, in a subsequent part of his appeal, he exclaims: "Thus dependent on every creature, and passive to every accident, can the world, the uncharitable world, be surprised to observe moments when the *blind* are at variance with themselves, and with every thing else around them? With the same instincts of self-preservation, the same irascible passions which are common to the species, and exasperated by a sense of debility, either by retaliation or defence, can the blind be real objects of resentment or contempt, even when they seem peevish or vindictive?"

The blind, however, are not without sources of consolation peculiar to themselves; of which, no one was more conscious than the amiable Blacklock, or more capable of forcibly detailing. "Their behaviour," says he, "is often highly expressive, not only of resignation, but even of cheerfulness; and though they are often coldly, and even inhumanly treated by men; yet are they rarely, if ever, forsaken of heaven. The common Parent of nature, whose benignity is permanent as his existence, and boundless as his empire, has neither left his afflicted creatures without consolation or resource. Even from their loss, however oppressive and irretrievable, they derive advantages; not, indeed, adequate to recompense, but sufficient to alleviate their misery. The attention of the soul, confined to those avenues of perception which she can command, is neither dissipated nor confounded by the immense multiplicity, nor the rapid succession of surrounding objects. Hence her contemplations are more uniformly fixed upon herself, and the revolutions of her own internal frame. Hence her perceptions of such external things as are contiguous and obvious to her observation, become more lively and exquisite. Hence, even her instruments of corporeal sensation are more assiduously cultivated and improved; so that from them she derives such notices and presages of approaching pleasure or impending danger, as entirely escape the attention of those who depend for security on the reports of their eyes. A blind man, when walking swiftly, or running, is kindly and effectually checked by nature from rudely encountering such hard and extended objects as might hurt or amuse him. When he approaches bodies of this kind, he feels the atmosphere more sensibly resist his progress; and, in proportion as his motion is accelerated, or his distance from the object diminished, the resistance is increased. He distinguishes the approach of his friend from far, by the sound of his steps, by his manner of breathing, and almost by every audible token which he can exhibit. Prepared for the dangers which he may encounter from the surface of the ground upon which he walks, his step is habitually firm and cautious. Hence he not only avoids those falls which might be occasioned by its less formidable inequalities; but, from its general bias, he collects some ideas how far his safety is immediately concerned; and though these conjectures may be sometimes fallacious, yet they are generally so true, as to preserve him from such accidents as are not incurred by his own temerity. The

rapid torrent and the deep cascade, not only warn him to keep at a proper distance, but inform him in what direction he moves; and are a kind of audible cynosures to regulate his course. In places to which he has been accustomed, he, as it were, recognises his latitude and longitude from every breath of varied fragrance that tinges the gale; from every ascent or declivity in the road; from every natural or artificial sound that strikes his ear: if these indications be stationary, and confined to particular places. Regulated by these signs, the *blind* have not only been known to perform long journeys themselves, but to conduct others through dangerous paths, at the dark and silent hour of midnight, with the utmost security and exactness."

The perfection to which the blind are capable of arriving in the use of those senses of which they remain in possession, is indeed truly admirable; and strongly manifests the bounty of nature, in providing new resources and enjoyments to compensate for any accidental deficiency. In the delicacy of their hearing and touch, the blind excel those who see, to a degree which is almost incredible; and renders them, in some respects, objects of envy. Their delicacy of ear renders them particularly susceptible of the enjoyment of music, and capable of attaining to the most consummate excellence in the practice of that delightful art. Of this, every age has afforded abundant proofs; from the rude period when *blindness* and *minstrelsy* were usually conjoined, to the present time. In the 16th century, Franciscus Salinas, a native of Burgos in Spain, who was afflicted with incurable blindness, obtained the greatest celebrity for his skill, not only in the practice, but also in the theory of music. His treatise on the scientific principles of harmony, according to sir John Hawkins, is equal in value to any that is yet extant. Caspar Crumbhorn, a native of Silesia, and Martini Pesenti of Venice, who flourished not long after, were also blind musicians, that excelled all their cotemporaries in their exquisite performance; and in their compositions both for instruments and the voice. To these we may add the well-known English organist, Stanley; who obtained the greatest celebrity in his day, both for his performance and his compositions. So delicate and susceptible was this gentleman's ear, that he was able to accompany any lesson with a thorough bass, though he had never heard it before; and thus anticipating the harmony before the chords were sounded, and accompanying it in a manner suitable to its nature.

In the sense of touch, the blind have a no less striking superiority over those that see, than in the sense of hearing. Many of them have been able to distinguish the various colours of cloths and other substances, by the delicacy of their fingers alone, without any assistance from their eyes. This was the case with Stanley, already mentioned; as well as with a French lady, blind from her infancy, whose accomplishments are particularly detailed in the *Annual Register* for 1762. Dr Blacklock, however, says of himself, that though "he tried repeated experiments, by touching the surfaces of different bodies; and examining whether any such diversities could be found in them, as might enable him to distinguish colours; yet no such diversity could he ever ascertain. Sometimes, indeed, he imagined that objects which had no colour; or, in other words, such as were black, were somewhat different and peculiar in their surfaces; but this experiment did not always nor universally hold." Stanley was an expert player at cards,

by means of packs which he previously prepared, by pricking them in several parts; yet so imperceptibly, that the closest inspection could scarcely discern his marks. The blind French lady likewise played at cards in this manner; she played also on the guitar; and contrived a way of pricking down the tunes, as an assistance to her memory. "So delicate are her organs," says the account, "that in singing a tune, though new to her, she is able to name the notes. In figured dances, she acquits herself extremely well; and in a minuet, with inimitable ease and gracefulness. As for the works of her sex, she has a masterly hand: she sews and hems perfectly well; and in all her works she threads the needles for herself, however small."

A still more extraordinary example of acquired dexterity, in spite of the most afflicting natural privations, was in the case of a lady, who, in consequence of a violent attack of the confluent smallpox, was completely deprived both of her sight and hearing, as well as of her speech, notwithstanding the medical aid of sir Hans Sloane. In this deplorable condition, her touch and her smell became so exquisite, that she could distinguish the different colours of silk and flowers; and was sensible when any stranger was in the room with her. After she became blind, and deaf and dumb, it was not easy to contrive any method by which a question could be asked her, and an answer received. This, however, was at last effected by talking with the fingers; at which she was uncommonly ready. But those who conversed with her in this manner, were obliged to express themselves by touching her hand and fingers instead of their own. She generally distinguished her friends by feeling their hands; which they presented to her, when they came in, as a means of making themselves known: the make and warmth of the hand produced, in general, the differences that she distinguished; but she sometimes used to span the wrist, and measure the fingers. To amuse herself, in the mournful and perpetual solitude and darkness to which her disorders had reduced her, she used to work much at her needle; and it is remarkable, that her needle-work was uncommonly neat and exact. She used also sometimes to write; and her writing was yet more extraordinary than her needle-work: the character was handsome, the lines were all even, and the letters placed at equal distances from each other: but the most astonishing particular of all, with respect to her writing, was, that she could by some means discover when a letter had by mistake been omitted; and would place it over that part of the word where it should have been inserted, with a *caret* under it. It was her custom to sit up in bed at any hour of the night, either to write or to work, when she was kept awake by pain, or any other cause.

These circumstances were so very extraordinary, that it was long doubted whether she had not some faint remains both of hearing and sight, and many experiments were made to ascertain the fact; some of which, when she accidentally discovered them, gave her prodigious uneasiness, on account of her being suspected of insincerity. At length sir Hans Sloane, after being permitted to satisfy himself by such experiments and observations as he thought proper, pronounced that she was absolutely blind and deaf.

If we may credit Leo Africanus, (l. 6.), there was a blind man who used to exercise the surprising office of conducting merchants through the sands and deserts of Arabia. His relation, however, is rendered far from

improbable, by what Dr Bew communicates in the first volume of the Transactions of the Manchester Society respecting John Metcalf, commonly known by the name of Blind Jack, whose death has been recently announced in the newspapers. Though this man had become blind at a very early age, he followed the profession of a waggoner, and occasionally of a guide in intricate roads during the night, or when the tracks were covered with snow. At length he became a projector and surveyor of highways, in difficult and mountainous districts; an occupation that we should suppose, would be the last to which a blind man would ever turn his attention. His abilities, however, in this respect, were so great as to procure him constant employment; and most of the roads over the Peak in Derbyshire, were altered by his directions. "With the assistance only of a long staff," says Dr Bew, "I have several times met this man, traversing the roads, ascending precipices, exploring valleys, and investigating their several extents, forms, and situations, so as to answer his designs in the best manner."

In respect of intellectual advancement, and extensive proficiency in the various departments of science and literature, there are many remarkable instances on record in the annals of the blind. Dr Blacklock, already mentioned, was an excellent classical scholar, a learned divine, and a pleasing poet. The celebrated Saunderson, it is well known, though totally destitute of sight, was able to make such proficiency in mathematics, that he discharged the duties of professor of that science, in the university of Cambridge, with great applause. The smallpox had so completely destroyed his eye-sight in early infancy, that he had no perception of light; yet so delicate was his feeling, that he was sensible of the slightest vicissitudes of the atmosphere; and while he assisted in the open air, at astronomical observations, he distinguished the times at which a cloud obscured the sun, by the impression of the air on his face. In passing over with his hands a cabinet of medals, he could detect the counterfeits, even though so well executed as to deceive the eyes of a connoisseur; and he judged of the exactness of a mathematical instrument, by passing his fingers over its divisions.

No less remarkable for his scientific attainments, was Dr Henry Moyes, a native of Fifeshire; of whom the world has been but lately deprived. He also lost his sight by the smallpox at so early a period, that he never recollected to have seen. Possessed, however, of a lively genius and an ardent application, he made great proficiency in almost every branch of liberal knowledge; and particularly in the various departments of chemistry, natural history, and natural philosophy. Mechanical pursuits were the favourite employment of his early years; and even when a boy, he was expert at the use of edged tools. When he afterwards became a lecturer on various branches of natural philosophy and chemistry, he performed most of the experiments which his course required, with his own hands, and with great neatness. He lectured also with the greatest precision and accuracy on the laws of optics, and the phenomena of light and colours; although it does not appear that his eyes had any proper perception of either. "The rays refracted through a prism," says Dr Bew (in the Manchester Memoirs), "when sufficiently vivid, produced certain distinguishable effects on his eyes. The red gave him a disagreeable sensation, which he compared to the touch of a saw. As the colours declined

in violence, the harshness lessened, until the green afforded a sensation that was highly pleasing to him, and which he described as conveying an idea similar to what he felt in running his hand over smooth polished surfaces. Polished surfaces, meandering streams, and gentle declivities, were the figures by which he expressed his ideas of beauty: rugged rocks, irregular points, and boisterous elements, furnished him with expressions for terror and disgust." Dr Moyes had long abstained from the use of animal food and fermented liquors; nevertheless, he was remarkable for the cheerfulness or equanimity of his temper; and greatly excelled in the charms of conversation.

That the blind should be able to discourse with accuracy on the general laws of optics, need not so greatly excite our surprise, when it is considered, that, except it be the mere perception of light and colours, these are all resolvable into the effects of impulse and attraction, in causing various deviations from the rectilinear course which luminous rays naturally pursue. Analogy, therefore, will in most cases supply the blind with means of satisfying themselves of the truth of an optical theorem. Diderot, in his *Lettres sur les aveugles, à l'usage de ceux qui voient*, mentions an extraordinary blind man whom he had seen at *Puisaux en Gatinois*, who was accustomed to express his ideas of visible objects, and of optical relations, in this analogical manner. He defined a mirror to be "a machine by which objects are placed in relief, out of themselves;" and he called the eye, "an organ upon which the air produces the same effect, as a stick does upon the hand." This analogical mode of expression, however, will be of little or no service where the simple notion of light or of colour is alone concerned, for the communication of which there is no avenue whatever but the eye; so that, when a man who has been totally blind from his infancy, discourses concerning light and colours, thus simply considered, his language must be like that of a parrot, without appropriate ideas annexed.

Dr Blacklock, however, in his poetical productions, alludes to the various beauties of the visible world, and to the charms and delicacies of colour, with all the propriety, and with all the rapture and enthusiasm, that ever fired the breast of a poet who had the fullest enjoyment of his eye-sight. Nor was this done mechanically, or merely by rote; for having himself put it as a question, "How shall we account for the same energy, the same transport of description, exhibited by those on whose minds visible objects were either never impressed, or have been entirely obliterated?" he assures us that, "however unaccountable this fact may appear, it is no less certain than extraordinary." This paradox seems to be explained with great ingenuity, and in a very satisfactory manner, by Mr Alison in his *Essays on Taste*.

"That the blind," says he, "may receive the same delight from the ideas which they associate with colours that they do not see, is a fact which I think every one will be convinced of, who reads the poems of Dr Blacklock. No man who is not acquainted with the history of their ingenious author, could perceive that he had the misfortune to lose his sight in early infancy. That from conversation, and from the perusal of books of poetry, it was possible for him to learn the distinguishing colours of certain objects, and to apply them with sufficient propriety in his own verses, I do not deny; but the circumstance of importance, at present, is this,

that his poetry is full of the same sentiments, and expresses the same admiration with regard to the different visible qualities of matter, with that of poets who had no such defect; and that the same power is ascribed to them in producing the emotions of beauty, and with as great accuracy with regard to particular instances, as in the compositions of those who have had the sense of sight in its fullest perfection. If our perception of the beauty of colours arose from some original fitness in such qualities to produce this emotion, it is obvious, that the blind must be as incapable of perceiving this beauty, as of perceiving the colours themselves; but if the beauty of colours arises from the associations we connect with them, this fact, in the case of Dr Blacklock, admits of a very simple solution. From reading, and from conversation, he has acquired the same associations with the words that express such colours, as we have with the colours themselves; that the word *white*, for instance, signifies a quality in objects, expressive of cheerfulness and innocence,—the word *purple*, the quality of majesty,—the word *black*, the qualities of gloom and melancholy, &c. In this case, it is obvious, that he may feel the same emotions from the use of these words, that we do from the colours which they express; and that, from the permanence of these associations in a great variety of cases, he may apply the terms with sufficient propriety, either in sublime or beautiful descriptions. As this is in reality the case, it seems to be a very strong confirmation of the opinion, that the beauty of such qualities arises from the associations we connect with them, and not from any original or independent beauty in the colours themselves." *Essay ii. chap. 3. sect. 2.*

From the instances we have now produced, it appears sufficiently evident, that the blind are susceptible of a very high degree of intellectual improvement; and are capable of attaining skill and dexterity in many mechanical employments. That a due degree of care and diligence should be bestowed upon their education and improvement, is strongly prompted by every feeling of humanity and generosity; and is, indeed, no more than they have a right to demand, from the justice and benevolence of their more fortunate fellow creatures. It is with pleasure we add, that their claims have not been slighted nor treated with neglect; and that the present age is highly distinguished by the attention that has been bestowed, upon the most eligible means of rendering these unfortunate persons useful to themselves and to society. In London, in Edinburgh, in Paris, and in many other great cities and flourishing towns, asylums have been erected for the indigent blind; where they are not only fed and clothed by charitable contribution, but instructed in a variety of trades, such as weaving, spinning, rope-twisting, &c., which it is found they can exercise in great perfection; and where also the cultivation of their moral and intellectual faculties is properly attended to.

It is not very long ago since the prejudice against the capacity of the blind was so great, that a descendant of the celebrated Lord Verulam, Mr Nicholas Bacon, who had the misfortune to lose his eyesight at nine years of age, and afterwards assiduously addicted himself to study, found great difficulty in procuring admission into the learned seminaries of Brabant, where he resided. This prejudice, however, he so completely overcame, that he was afterwards created doctor of laws in the city of Brussels, with high approbation; and hav-

ing commenced pleading counsellor, or advocate in the council of theabant, he had the pleasure of terminating almost every suit in which he was engaged, to the satisfaction of his clients. It may, nevertheless, be doubted, whether the profession of a barrister affords a sufficiently promising opening for the abilities of a blind man, to induce him to devote himself to such a pursuit.

We read also of a celebrated blind sculptor in the *Cours de Peint* of De Piles, who took the likeness of the Duke de Bracciano in a dark cellar, by means of moulding his face in wax; and who made a marble statue of king Charles I, with great elegance and justice: yet we would not from all this infer, that the blind are well qualified to excel in sculpture. A sufficient variety of liberal pursuits, however, will still remain within their reach, in the various departments of natural philosophy, mathematics, chemistry, theology, and the belles lettres; in all of which we have seen that they are well qualified to excel: and in the fine art of music, their eminence has been unrivalled.

A variety of expedients have been devised for facilitating the studies of the blind, and rendering that readily intelligible to the touch, which, in those who see, is addressed only to the eye-sight. It is well known, that the celebrated Saunderson had contrived for himself a machine, by which he greatly facilitated his arithmetical calculations, as well as his geometrical studies. Of this kind of palpable arithmetic, he has himself given an account; and it is much more minutely described in Diderot's Letters on the Blind, already mentioned. It consisted of a square board of a convenient size, divided by parallel lines into a considerable number of smaller squares. Each of these smaller squares, or separate departments, was pierced with nine holes, standing in three parallel rows; and by fixing a pin in one or other of these nine holes, the nine digits were denoted, according to the position of the pin. In order to facilitate his calculation, Saunderson made use of two sizes of pins, a larger and a smaller. The pins with large heads were always placed in the centre holes of the squares; and when they stood alone, without any small pins, they denoted the cypher. The number 1 was denoted by a pin with a small head, placed in the centre of a square; the number 2, by a large pin in the centre, and a small one at the side, in the hole which was first in order; the number 3, by a large pin in the centre, and a small one in the second hole at the side; and so on in order, to the number 9. By this means, it is evident that any sum could be expressed, in a number of squares corresponding to the number of its figures; and thus, all the arithmetical operations performed. Saunderson, it is said, possessed wonderful facility in the use of this machine; and was accustomed also, by means of it, to form diagrams for his geometrical demonstrations; the pins serving the purpose of making the angles of the figures, either alone, or with silk threads stretched between them.

An arithmetical machine was also contrived by Mr Grenville, who lost his eye-sight, consisting of a square board furnished with ten sets of pegs of different forms, corresponding to the nine digits and cypher. But by far the most simple and commodious of these machines, seems to be that invented by Dr Henry Moyes for his own use; of which he has himself inserted an account in the *Encyc. Brit.* 3d. edit. He informs us, that when he began to study the principles of arithmetic, he soon found that a person deprived of sight

could scarcely proceed in that useful science, without the aid of palpable symbols representing the ten numerical characters; and being then unacquainted with Saunderson's method, he embraced the obvious, though, as he afterwards found, imperfect expedient, of cutting into the form of the numerical characters, thin pieces of wood or metal; which being arranged on the surface of a board by means of a lamina of wax, readily represented any given number. It soon, however, occurred to him, that his notation, consisting of ten species of symbols or characters, was much more complicated than was absolutely necessary; and that any given number might be distinctly expressed by three species of pegs alone, viz. two with heads of the form of a right-angled triangle, and distinguished from each other by having a notch cut in the oblique side or hypotenuse of one of them, their other two sides being, one of them a continuation of the peg, and the other at right angles to it; and the third peg having a head of the form of a square. These pegs were to be stuck into a board of about a foot square, and divided into 576 little squares, by lines which were cut a little into the wood, so as to form a superficial groove. At each angle or intersection of the grooves, a hole was made for the insertion of the pegs. Sixty or seventy of each kind of pegs were necessary, which were placed in a case consisting of three boxes or cells, one for each set.

"Things being thus prepared," says the Doctor, "let a peg of the first set (with a plain triangular head) be fixed into the board; and it will acquire four different values, according to its position respecting the calculator. When its sloping side is turned towards the left, it denotes one, or the first digit; when turned upwards, or from the calculator, it denotes two, or the second digit; when turned to the right, it represents three; and when turned downwards, or towards the calculator, it denotes four, or the fourth digit. Five is denoted by a peg of the second set (with a notched triangular head), having its sloping side, or hypotenuse, turned to the left; six, by the same turned upwards; seven, by the same turned to the right; and eight, by the same turned directly down, or towards the body of the calculator. Nine is expressed by a peg of the third set (with a square head) when its edges are divided to right and left; and the same peg expresses the cypher, when its edges are directed up and down.—When it is necessary to express a vulgar fraction, I place the numerator in the groove immediately above, and the denominator in that immediately below the groove in which the integers stand; and in decimal arithmetic, an empty hole in the integer groove represents the comma or decimal point. By similar breaks, I also denote pounds, shillings, pence, &c.; and by the same expedient, I separate, in division, the divisor and quotient from the dividend. Coefficients and indices, in algebra and fluxions, are supplied upon similar principles."

Various attempts have been made to supply the blind with tangible musical characters, or signs, by which their progress in the acquisition of an art which affords them so great delight, and for which they are so peculiarly qualified, might be materially facilitated. We do not think, however, that these attempts have been attended with the same success, as in the case with the palpable arithmetic. In Tansure's *Musical Grammar*, p. 93. it is recommended, that the blind musician should be provided with a smooth board with ledges of deal glued on it at proper distances, to represent the five

lines of the musical staff; with such additional lines as occasion may require. In these ledges, as well as in the intervals between them, a number of holes are to be drilled for the reception of a variety of pegs of different forms, intended to indicate the various kinds of notes in music; such as semibreves, minims, crotchets; together with the rests, flats, sharps, bars, &c.

In a contrivance of Mr Cheese for the same purpose, and which we have seen actually introduced into some asylums of the blind, a stuffed cushion is substituted for the board of Tansure, upon which strings are sewed to represent the musical staff, and the pegs intended to denote the various musical characters, are fixed upon sharp pointed wires, by which means they may be stuck into any required part of the cushion. What we chiefly object to this contrivance, is the multiplicity of pegs, of awkward and arbitrary forms, which it employs, the ready use of which cannot be taught to the blind without a great deal of trouble. Instead of this, we think it would be better to have the heads of the pegs formed into a resemblance of the notes, rests, bars, shakes, &c. which are actually employed in written music, which are sufficiently simple and intelligible, and far from being too numerous, as they have a relative value from their position, as well as an absolute one from their form.

In the year 1786, an *Essay on the Education of the Blind* was printed at Paris, under the patronage of the Academy of Sciences. It is the composition of M. Haüy, and does great honour to the author, on account of the comprehensive and liberal views which it exhibited. It contains a detail of a great variety of expedients by which the blind may be successfully instructed in many of the mechanic arts, as well as in music, arithmetic, geography, &c. and may even be taught to read, write, and print. In order to instruct the blind in music, at the institution of which M. Haüy communicates the details in this work, musical characters of every necessary form were cast in metal, and so many in number as to represent upon paper, by elevations on its surface, all the possible varieties that occur. In teaching geography, which was the department of M. Weissenbourg and Mad. Paradis, the circumference of countries was marked out by a tenacious and viscid matter, and the different parts of the maps was covered with a kind of sand, mixed with glass, in various modes; the order of the towns being distinguished by grains of glass of a greater or less size; or, according to the plan of M. Haüy, the limits of the maps, for the use of the blind,

were marked by a small rounded iron wire; and by some difference, either in the form or size of every part of a map, the pupils were assisted in distinguishing one part from another.

The manner in which the blind are taught to write and print, is as follows: The pupil, by repeated experiments, having familiarised himself to the forms of the letters as drawn in relief, both in their direct and inverted position, gradually learns to impress them upon strong paper, a little moistened, with the point of a blunt iron pen or *stylus*, which marks without piercing the paper. By this means the letters become perceptible to the touch, on the one side sunk, and on the other *in relief*; and thus the blind may be enabled to form and decipher, not only the characters required in common language, but also mathematical diagrams, geographical plans, and all the characters employed in arithmetic, music, &c. In printing, the blind compositor has a box for every letter, on the outside of which is marked in relief, the peculiar character belonging to each. By this means he is enabled readily to choose and arrange his types, and when they are set, he makes use of a strong paper, slightly moistened, like that employed in writing, in order to render it more easily susceptible of impressions. Having laid this upon his types, by the operation of the press, or the strokes of a small hammer, he raises an impression upon the paper, which, when dry, is sufficiently obvious to the touch, to enable the blind to read by their fingers, and is so durable as to be by no means easily effaced. This method of printing, it is evident, is also legible by the eye-sight; and it has one advantage over that in common use, that the types are set not in the reverse, but in the direct order, so that the characters may appear *in relief*, in the same order, on the opposite side of the paper. Dr Blacklock mentions, that he was in possession of a copy of M. Haüy's *Essay*, which was printed in the manner now described, and also bound by the blind pupils of the Parisian institution, with great neatness. An English translation of the *Essay* is annexed to the edition of that gentleman's poems, printed at Edinburgh in 4to, in 1793.

See *Journal des Sçavans*, Nov. 19th 1685, which contains James Bernoulli's method of teaching mathematics to the blind. (m)

BLITUM, a genus of plants of the class Monandria, and order Digynia. See BOTANY. (w)

BLOCK.

Is the name given to a pulley, or system of pulleys, mounted in a frame or shell, but considering them as detached from the ropes which run through them. When speaking of the block with its rope, the seaman uses the phrase of a tackle of single or double blocks; hence the term block is applied to the pulley or pulleys, with its frame or shell, and its band or strap.

The ship's block consists of its sheaves or pulleys, which are circular pieces of wood (usually lignum vitæ,) or some times brass or cast metal, with a groove, turned on its edge for the reception of the rope; and in the best blocks, called coaked sheaves, the sheave has a brass bush fitted into the centre, with a hole through it

to receive the pin on which the sheave revolves. The pin is made of lignum vitæ, cocus, or a West India wood called green heart; but the best blocks have iron pins. The pin is supported by passing through the sides of the shell of the block, which is made of elm, ash, or other tough wood, with a hole morticed through it to receive the sheave, and confine it to revolve steadily though freely upon its pin, and at the same time keep the rope from getting off the groove in the edge of the sheave. When the block contains two or more sheaves, as many mortices are made. Sometimes the same pin serves all the sheaves; and at other times, the sheaves are placed one above the other, having of course sepa-

rate pins. The strap is a rope, or, in some cases, a band of iron, encompassing the shell of the block, in a notch or scoring cut round the block to receive it: The strap terminates in an eye of rope, or hook of iron, by means of which one of the blocks of a tackle is attached to the object upon which it is to act as a mechanical power, while the other block is suspended from some fixed support. The former is called the running block, and the latter the standing block.

The blocks in use among shipping are so numerous, having different names according to the purposes to which they are applied, and the manner in which their straps and tackles are fitted up, that a mere enumeration of all their names would take considerable room. They may, in general, be divided into single, double, triple, and four-fold blocks, according to the number of sheaves they contain. The shells of very large blocks are made of separate pieces of wood, as the cheeks of the shell, its partitions, &c. These are called *made blocks*. The shell is formed of several pieces of elm plank, suited to the thickness of the cheeks, sheave holes, and partitions, and is strongly bolted together by three bolts at each end, driven through and riveted with a washer at the points.

Blocks are again divided into thick and thin blocks; the former being intended to receive large ropes, and the latter smaller ones. The following may serve as a general idea of the mode of making any of the common kinds of blocks in the old way, before the introduction of machinery. The shells being sawn to their length, breadth, and thickness, the corners or angles are sawn off. The workman then gauges or marks out the size of the sheave hole in the middle, one sixteenth larger than the thickness of the sheave, and once the thickness longer than the diameter, for a single sheaved block. In blocks of two sheaves, the partition is kept in the middle, and is one sixth less than the sheave hole; each sheave hole is gauged on the two opposite sides, and in the same manner for blocks with a greater number of sheaves. The blocks are then jamed up edgewise with wedges in a clave or frame, and the sheave holes are made in this manner; the length and breadth are first gauged out, and holes are bored half way through the block, along the part gauged out, with an augur of the size of the sheave hole; then the sheave hole is gauged, and bored on the opposite side in the same manner, so as to meet the opposite holes. Blocks from ten inches and upwards have one hole bored at each end, and cut through with a chisel, and the wood is sawed out with a rib saw. All blocks have the sheave holes cleared through by chisels, and by burrs at the corners. Blocks that are to have iron straps should have the strap fitted on before the wood is cut out of the middle. The hole for the pin is bored through the middle of the block, one-tenth less than the diameter of the pin. The outsides and edges of the shell are next rounded off by the stock sheave, and neatly finished by the spoke sheave. In the royal navy, blocks are left thick upon the edges of the cheeks; but in the merchant ships, the edges are somewhat thinned off to a small square, and somewhat rounded off. The scores which are the grooves to receive the strap, are gauged out along the outsides of the cheeks and tapered in depth, from nothing at the pin to half the thickness of the strap at the ends of the block for a single score, and the same on each side of the pin for double scores, which are made when the block is to have double straps. The

scores are gauged down across the breast of the block to half the size of the strap, in order to allow for the serving. After the score is cut, the sheaves are fitted; they are one-tenth thicker than the diameter of the rope intended for running on them, and five times that thickness in diameter. The hole for the pin should be bored through the centre of them by a bit fixed in the mandrel of a turning lath, or with a stock and bit, and opened out with an auger one sixteenth larger than the pin, that it may easily turn. They are then put in a lath, and turned smooth, and the outer circumference hollowed one-third of its thickness, that the rope may embrace it closely. The diameter of the pin is the thickness of the sheave, and is turned in a lathe, except its head, which is left octagonal to prevent its turning in the block, and the pin is driven through the holes in the block and sheaves. After the sheaves are fitted, the inside of the sheave hole, at one end of the block, is gauged hollow to admit the rope, and correspond with the sheaves; and a small neat chamfer is taken off the edges. The following articles will explain some of the different kinds of blocks used in shipping:

Snatch block, is a single sheave, with a notch cut through one of its cheeks, to admit the rope or fall to be lifted in and out of the block without putting its end through first. (See a figure of this in Plate LVII. Fig. 1.) The strap does not in this surround the block, but is put through a hole bored through the divided end. The figure is represented with two tails, which may be made up for a hook, a thimble, or eye, according to the situation where it is to be used, which is generally for the main or fore sheet blocks of square rigged vessels. It is a convenient block for heaving any rope in the navy. The snatch blocks are iron bound, terminating at the notched end of the block, with a swivel hook or an eye-bolt, large enough to receive several turns of lashing, which fastens the block to its fixed support. That part of the strap over the notch in the side lifts up with a hinge, and is confined down, when the rope is in the block, by a small pin put across through the end of the pin of the sheave, which projects up from the block sufficiently to pass through an eye made in the hinge part of the strap. The strap on the other part of the block is let into the block, and confined by the pin and some nails. These blocks are used for heavy purchases, where a warp or hawser is brought to the capstan. See Plate LVII. Fig. 2.

Deep sea line block, is a small wooden snatch block, about from nine to eleven inches long.

Cheek blocks are half shells, bolted against the mast heads; the chief bolt serves for the pin of the sheave; they receive the halyards and stays of their respective masts.

D blocks, are lumps of oak in the form of the letter D, from 12 to 16 inches long, and 8 or 10 feet wide; they are bolted to the ship's side in the channels to receive the lifts.

Long tackle block, are two single sheaves placed one above the other in the same shell. (See Fig. 3. Plate LVII.) The lower sheave is only $\frac{2}{3}$ ds the size of the other; it is used in combination with a common single block, to form the long tackle, for loading, or any other purchase. In the navy and East India service they are used as yard tackles. The rope is reeved through it in the same manner as it would be through a common double block; but it is preferred where it is convenient, because the strap being in the centre of the resistance.

it hangs more steadily than when the sheaves are on one pin.

Clue garnet blocks. These are single sheaves suspended from the yards by a strap with two eyes; a lashing surrounds the yard and passes through the eyes, so as to suspend the block beneath the yard; these blocks receive the clue garnets or ropes which haul up the clues of the sail; this is applied to the main and fore yard.

Clue line blocks are for the same purpose as the preceding, but applied to the top-sails, top-gallant, and sprit-sails. A great improvement has lately been made in these blocks, by Mr Brunel, inventor of the block machinery at Portsmouth. The old clue line and clue garnet blocks, (for they are the same except in size,) was a single sheave block, strapped with two eyes as above; a knot was made in the end of the clue line or garnet, just at the place where it was attached to the clue of the sail, to prevent the corner thereof being drawn into the block. This was not effective, and frequent inconvenience arose; for the sail being so constantly in motion, the rope had a great tendency to get entangled with the sail, and drawn over the sheave. The improved block in question is shewn in Plate LVIII. Fig. 1. The two holes at *aa*, are where the rope goes in and out again. The sheave is situated in the centre of the block, so as to be wholly inclosed, except a mortice at *b*, where the sheave is put in. The strap surrounds the lower part of the block; then both ends pass through a hole in the upper part about *c*, crossing each other. They are then formed into an eye, by which the block is suspended from the yard. By this means no accident can happen, as the garnet, or rope, is so inclosed in the block, that it cannot be deranged by any violence, nor the sail be drawn into the block.

Main sheet block is used for the sheet tackle of the main-sail-booms of small vessels. The pin projects from each side of the block, being in all the same length as the block; the fall or rope of the tackle is belayed or twisted round this pin, to stop it. This block is either single or double, and has a hole through the end to receive its strap.

Monkey blocks are sometimes used on the lower yards of small merchant ships, to lead (into the mast, or down upon the deck) the running rigging belonging to the sails. The shells are made of ash or elm. Some are only small single blocks attached by a strap and iron swivel to iron straps, which embrace and nail to the yard the block turning to lead the small running ropes in any direction; others are nearly eight square, with a roller working in the middle; and a wooden saddle beneath to fit and nail to the yard.

Nine pin blocks are used to lead the running ropes in an horizontal direction. The shells, made of ash or elm, resemble the form of a nine-pin, though flattened on the sides. Their lengths are generally confined to the place in which they are fixed; and this is for the most part under the cross pieces of the fore-castle, and quarter-deck bitts. The breadth of the block, sheave, &c. is governed by the rope, and taper at the ends to three-eighths of the breadth of the middle; the pins at each end serving as a vertical axis, is two-thirds of the size of the end. The thickness is five-eighths of the breadth. These blocks may be turned in a lathe, and flattened afterwards with a spoke sheave.

Rack blocks, are a range of small single blocks, made from one solid, by the same proportions as single

blocks, with ends in form of a dove's tail for the lashing by which they are fastened athwart the bowsprit, to lead in the running ropes: they are seldom used.

Shoe blocks, are two single blocks, cut in a solid piece, transversely to each other; they serve for legs and falls of the bunt-lines, but are seldom used.

Shoulder block, is a large single block, left nearly square at the upper end of the block, and cut sloping in the direction of the sheave. Shoulder blocks are used on the lower yard arms, to lead in the topsail sheets; and on topsail yards, to lead in the topgallant sheets, and by means of the shoulder are kept upright, and prevent the sheets from jamming between the block and the yard; they are also used at the outer end of the boomkins, to lead in the foretackle. See Plate LVIII. Fig. 2.

Sister blocks, are similar to two single blocks, and are formed out of a solid piece, about 20 inches long, one above the other. Between the blocks is a scoring for a middle seizing: A round head is turned at each end, and hollowed underneath to contain the end seizings; along the sides, through which the pins are driven, is a groove or scoring, large enough to receive part of the topmast shrouds, in which it is seized. These blocks receive the lifts and reef tackle pendants of the topsail yards.

Spring block, a new kind of block, invented by Francis Hopkinson, Esq. of Philadelphia, and designed to assist a vessel in sailing, by increasing the acting spring of her rigging. It is proposed to apply it to all such parts of the rigging as will admit of it with safety and convenience, and where its operation will be most advantageous, but particularly to the sheet ropes, and, if practicable, to the dead eyes, in lieu of what are called the chains. A, (Plate LVIII. Fig. 3.) is a block made in the usual manner, having a ring or eye B at one end; *c* is a spiral spring linked at one end to the hook DE, and at the other to the ring F, which is to be annexed to an eye-bolt at the timber-head, or by some other means, to the place where it is to be applied. The spring *c* must be of well tempered steel, and proportioned in strength to the service it is to perform. When used, two of these blocks are employed, one attached to the timber-heads and the other to the sail. Within the cavity or pipe, formed by the spiral spring, there must be a chain of suitable strength, called a check chain, (represented in the centre of the spring,) connected by the links to the hook DE and ring F. When the spring is not in action, this chain is slack; but when the spiral spring is extended by the force of the wind, as far as it can be without danger of injury, the check chain must then begin to bear to prevent its further extension, and if strong enough, will be an effectual security against failure. The inventor of this machine apprehends, on good grounds, that a vessel thus furnished will be less liable to heel; and that she will receive the impulses of the wind to better advantage, and sail with a more lively and equable motion, than if rigged in the common way. We have never heard of its being tried; but fear the weight of a spring sufficiently strong to have any effect on a large sail, would be very unmanageable, particularly aloft, from its weight, and would also be very expensive. There is no doubt if this, or a similar contrivance, could be applied to a sail, it would have a good effect: for instance, when a ship is sailing with a certain rate, if a sudden blast of wind comes, but does not continue, it will not advance the vessel at all; because it

does not continue long enough to communicate an increased momentum to so large a mass as a ship, though, at the same time, it may make her heel or pitch violently. If her rigging is fitted with these springs, she would receive the impulse of the same blast in a regular and progressive manner, which would tend to increase her velocity instead of causing her to heel. We think it would be very improper and dangerous to apply any thing of this kind to the shrouds. We recollect meeting with a similar invention, to be effected by a cylinder, fitted with a piston, which, when drawn out, would cause a vacuum, and act as a strong spring. By this means a sufficient elastic force might easily be obtained; but it would be difficult, nay, impracticable, to preserve such a cylinder in an acting state at sea, unless it were situated beneath the deck, and defended from the weather, &c., and then it could not be applied to the upper sails.

Strap bound blocks, are single blocks, with a shoulder left on each side, at the upper part, to admit the strap through a little above the pin. These blocks are used at the clues of the square-sails for the clue-garnets, or clue-lines; and under the yards, the shoulder preserves the strap from chafing.

Thick and thin, or quarter block, is a double block with one sheave, thicker than the other, and is used to lead down the topsail-sheets and clue-lines.

Although these are used for the topsail-sheets, and intended for the clue-lines, a single block would be cheaper and better, as the thin sheave is seldom used for the clue-lines, it being found rather to impede than to facilitate. Small ships in the merchant service have a double block lashed in the middle of the yard as the quarter block, through which the sheets reeve, and lead down on opposite sides. Large ships in the merchant service have a single block lashed on each side of the middle of the yard, and the sheets reeve on their respective sides, and lead down by the mast.

Block royal or viol, is a single sheaved block. The length is ten times the thickness of the sheave hole, which is three-eighths more than the thickness of the sheave; the thickness of the sheave is one-tenth more than the diameter of the viol; and the diameter of the sheave is seven times the thickness. The breadth of the block should be eight times the thickness of the sheave, and

the thickness two-sevenths of the length. This block is double scored, the sheave is coated with brass, and the pin is iron, and nearly as thick as the sheave. It is used in heaving up the anchor. The viol passes round the jeer capstan, and through the block which is lashed to the main-mast, and the cable is fastened in a temporary manner to the viol in several places. It is seldom used except in the largest ships of the royal navy.

The blocks lashed to a ship's principal yards, are as follow :

To the *lower yards*. The *jeer* block; *buntline* blocks; *leech line* block; *lift* blocks and *top-sail sheet* blocks, strapped together; *quarter* and *slab-line* blocks, strapped together; *clue garnet* blocks; *tricing* blocks; *pre-venter brace* blocks; *pendant* blocks; *studding-sail hal-yards* blocks.

To the *top-sail yards*. *Buntline* and *tye* blocks, strapped together; *top-gallant sheet* block and *lift* block, strapped together; *jewel* block and *brace-pendant* blocks; *clue line* blocks, and block to lead down the *top-gallant sheets*.

To the *top-gallant yards*. *Jewel*, *clue line*, and *brace pendant* blocks.

To the *mizen-yard*. *Jeer* block; *derrick* block; *signal halyard* block; *throat brail*, *middle brail*, and *coak brail* blocks.

To the *cross-jack yard*. *Quarter* blocks; *jeer* blocks; and *lift* and *top-sail sheets* blocks, strapped together.

To the *bowsprit*. The *bee* block, bolted to the bowsprit at the outer end under the bees; *fore bowline* blocks, lashed on each side the fore stay collar; *fore top-sail bowline* block, lashed to an eye bolt in the bowsprit cap.

Fish block, is hung in a notch at the end of the davit, and serves to haul up the flukes of the anchor to the ship's bow.

Girt-line blocks, in rigging the fore mast and main and mizen masts, are lashed round the mast-head, above the top of the cap; one to hang on each side. The girt lines that reeve through them, lead down upon deck for hoisting the rigging, tops, and cross-tree, and the persons employed to place the rigging over the mast-head.

Cat block, is employed to draw the anchor up at the cat head. (J. F.)

BLOCK MACHINERY.

THE immense number of blocks employed in the navy, and the great importance of having them accurately and substantially made, in order to insure their ready performance in every unfavourable situation which the tackling of a ship is exposed to in bad weather, render the manufacture of these articles of far more importance than the generality of our readers would imagine, from the appearance of so simple an implement. Cases constantly occur at sea, in tempestuous weather, where the failure of a single block may put the vessel in imminent danger, by preventing the setting of her sails, or other important operations. At all times, the saving of labour on board a ship will be very great, from having the numerous blocks of her rigging well made; for it is well known to mechanics, that, in any system of pulleys, a considerable portion of the purchase they would otherwise exert, is lost in the friction of the sheaves

upon their pins, and against the inside of the shell of the block, as well as in overcoming the rigidity of the ropes; for these, if tight laid, that is hard twisted, will not readily bend over small sheaves, but will take a considerable power to force them into the sudden curvature. Hence it follows, that blocks, with small pins made of iron, the sheaves large, and coated or bushed with metal, and all points of contact of the sheaves and shell made accurately, and using slack made ropes, will be the best means of diminishing the friction, and, at the same time, rendering the apparatus durable, a circumstance of equal importance to the seaman.

These and other circumstances, induced government in 1802, on the recommendation of general Benthams, to attend to the suggestion of Mr Mark Isambard Brunel, a gentleman who had at that time invented and taken out a patent for a complete set of machines for the

manufacture of every part of ship blocks. He consequently employed Mr Maudslay of London to erect from his designs an extensive suite of machinery in the arsenal at Portsmouth, for the fabrication of these articles.

These machines were set to work in 1804, and have been in constant use ever since. They consist of 44 machines, forming in the whole the most complete and perfect system of manufacture by machinery, of any establishment which is to be met with in this kingdom, or perhaps in the whole world, at least of an article which has so many different parts to be formed in hard materials, and has such a great variety of sorts and sizes to be made by the same machines, not less than 200 kinds of blocks being manufactured at these works. The mechanical contrivance, as well as the elegant construction of the block machines, is at least equal, if not superior, to any examples of practical machinery, which we have at present contemplated for the succeeding volumes of our work. Under these circumstances, we do not think our readers will require from us any apology for extending this article beyond the bounds which the manufacture of a ship's block alone would deserve. To our mechanical readers, this article, and its accompanying Plates, will be highly acceptable, as presenting them with a number of curious machines, which may in their hands, at the expiration of the patent, be rendered applicable to a great variety of other similar operations in the mechanical arts, which are now performed by manual labour.

Before proceeding to the detailed description of the drawings of the most striking of these machines, we shall give a general outline of the operations which a block and its sheave, or shiver, are subjected to, that the connection of one machine with another may be more clearly understood. The machines are put in motion by a capital steam-engine of 32 horses' power, erected by Messrs Boulton and Watt. The whole establishment contains 44 machines, as before stated, which form three sets, that is, three blocks of different sizes may be proceeding in all their stages at the same time, though in some of these stages one machine operates at the same time upon two, or even ten blocks. The building or block mill is of great length, having the steam-engine in the centre, which therefore divides the house into three lengths: the centre, which is a large and tall house, for the engine, and two wings for the mills. One of these wings is devoted to the machinery for sawing and converting the timber into scantling, that is parallelopipedons, of the proper size to form the different blocks; this department contains seven large sawing machines. On the opposite side of the building are the machines which form the blocks and their sheaves: These are smaller and more delicate engines, being 37 in number. It is to these we shall chiefly turn our attention in this article, because they are the real block machinery; the other seven, though no less deserving of notice from their ingenuity, and perhaps superior from their general utility, are only *sawing-machines*, and equally applicable to sawing wood for any other purpose besides block making: We shall therefore take a future opportunity of presenting our readers with these, or at least the most curious among them. See *SAWING Machinery*.

To trace the whole process from the tree to the finished block, we shall commence with—No. 1. The

straight cross-cutting saw. This is a saw operating very nearly in the same manner as the carpenter's hand-saw. The timber is brought to the mill in long trees, (of elm for the shells of the blocks,) with their sides rudely squared by the chip axe, so as to become irregular octagons in their transverse section; these are drawn by the machine upon a long horizontal bench, which is situated in the yard; and one end of the tree is brought through the window against which the machine is placed, and, being adjusted to their proper place, is cut across by the saw; exactly the proper length being cut off the end of the tree to form the shell of that kind of block for which the piece of timber seems best adapted, either as to its size or quality. This machine is only used for the largest trees.

No. 2. The *circular cross-cutting saw*, is for exactly the same purpose as the former machine, but is applied only to the smaller trees: It is a very curious piece of mechanism, difficult to be described in words. The timber is brought as before, through the window. The saw is a circle, with its axis parallel to the length of the tree. This axis is so mounted in a curious form, that it can be moved in all directions, either raised up, or moved sidewise; but in all these motions its axis continues parallel to itself, and the saw continues in the same plane. The saw continues in rapid motion by the mill; and the attendant applying the saw, by means of turning a handle, to the side of the tree, which it cuts into about one-third the diameter of the saw, and perhaps half through the tree, then he does the same on the top of the tree, next on the opposite side, and lastly beneath, if it is necessary, till the wood is quite cut across from its different sides. By this means a tree could be divided by a saw, which could not be of sufficient diameter to reach through from any one side.

No. 3. The *reciprocating riving saw*. The blocks cut by the last machine are here cut in the direction of the grain of the wood, first into two, three, or more pieces, in one direction, and then in a direction perpendicular to the former, so as to reduce the logs into the size for the scantling of the required block. This saw is on the same principle as that in common use in America and other countries, and which has often been described; but the construction of the machine is somewhat different. The largest blocks only are sawn or ripped up by this saw; the smaller ones being cut in the next machines, which are

No. 4. The *circular riving saw*. They have four of these, each consisting of a circular saw, projecting partly up through a table similar to a carpenter's bench. The pieces of wood being applied to the saw, are cut through the length of the grain, and divided into the proper scantling, in the same manner as by the foregoing machine; but this is applied to the smaller sizes.

These are the machines appropriated for converting the timber, and occupy one of the wings of the buildings. The parallelopipedons which are formed here, are carried to the opposite wing of the mill, where the machines for forming them into blocks are situated. They are as follow:

No. 5. The *boring machines*. The blocks thus sawn out, are fixed into a frame, and two centre bits are applied; one to bore a hole for the centre pin, and the other, perpendicular to this, can be brought to bore a hole for the commencement of the mortice which is to contain the sheave; the latter borer can be so fixed as

to bore either one, two, or three holes, according as a single, double, or threefold sheave block is wanted. Five of these machines are used.

No. 6. The *morticing machines* are most ingenious and perfect pieces of mechanism, which might be applied to many other useful purposes; each gives motion to chisels, which mortice out the cavities for the reception of the sheaves in two blocks at the same time, if single or double blocks; but in morticing threefold blocks, only one is done at once. Three of these machines are used.

No. 7. The *corner saw* cuts off the angles of the parallelepipedons which have passed through the above machines. There are three of these machines.

No. 8. The *shaping engine* is a curious engine, in which ten blocks, previously morticed, and with their angles taken off, are fixed by their extreme ends, between the rims of two equal wheels fixed upon the same axis. These having a rapid rotatory motion given them, the blocks are successively brought against the edge of a fixed gouge, which forms the outsides of all the twelve blocks to the segment of a large circle, which they describe by their rotation with the large wheels. The gouge has also a progressive motion following the curvature the block is intended to have. When this is done, all the blocks, by an instantaneous movement, are turned half round, so that the sides which were towards the centre of the circles are now brought outside; and the whole machine being again turned about, these sides of the blocks are formed by the same means as the former. The shaping machine, therefore, forms the outside of the blocks to their proper figure. They have three of these engines for different sized blocks, though either of the machines will receive several sizes, among which the differences are small and progressive.

No. 9. The *scoring engine* forms the scoring of the blocks, which is a groove round its largest diameter, for the reception of the strap of the block. This groove is shallow, where it passes over the ends of the pin of the block, and at one end; but at the other end, it is of considerable depth. Only two of the scoring engines are required, as they will admit a great latitude of different sizes, and they perform so quickly, as to score all the blocks made by the other machines.

The foregoing machines are appropriated to the formation of the shells of the blocks. Afterwards they are trimmed, polished, and finished by hand, as the surfaces are somewhat rough, though exactly the true shape and size; and this is almost as expensive an operation as any of the preceding, not because the blocks require much to be taken off to make them smooth, but because this process cannot derive any assistance from machinery, while the expense of labour in the machine work is so exceedingly small.

We now come to enumerate those machines employed for making the sheaves. The wood for these is cut from a tree of *lignum vitæ*, across the grain, so as to form pieces approaching to a circular figure, and nearly the thickness of the intended sheave. These pieces are cut by two machines. The first of these,

No. 10. The *straight saw*, for converting the *lignum vitæ*. This is constantly moving backwards and forwards by the machinery, in a horizontal plane. The tree of *lignum vitæ* is fixed vertically, and raised so much above the plane of the saw as the thickness of the intended sheave; and the saw being applied to the wood, quickly cuts it through, separating a piece from the end

of the tree, just the true thickness to form the sheave. This saw is appropriated to cutting out the largest sheaves, because the circular saw, to be next mentioned, would not act freely through a large and hard substance.

No. 11. The *circular saw* is for the same purpose, but is applied to the smaller sheaves. The tree is, as in the former instance, fixed in a vertical position, but upon the end of a spindle, in such a manner that it can revolve upon its own axis, and the circular saw has its axis placed vertically, and mounted in a frame which moves upon a centre, so that the saw moves in an arc of a circle, but still continues in the same plane. The saw, as it revolves, is applied against the tree, by moving it in its arc, and cuts off a thin plate. These plates are now sorted out as to the sized sheave which each will make with the least waste: They are then carried to,

No. 12. The *crown saw*. This is a saw similar to a trepan, and having a centre bit in the axis of it. The piece of wood being fixed by a neat contrivance before this saw, it is applied against the wood, and quickly cuts out a circle, and at the same time forms the centre hole, exactly in the centre of it.

No. 13. The *coaking engine* is perhaps the most ingenious of all these machines. It forms, by means which we cannot describe without the drawing, the cavity in the centre of the sheave for the reception of the coak or metal bush. This cavity is in the form of three small semicircles, arranged at equal intervals round the circular holes formed in the last machine. Two of these engines are used. The sheaves are cut by this engine, first on one side for one of the coaks, and they are then turned to have the other cut. The coaks are now inserted into the cavities cut by the coaking engines. They are cast of a mixture of copper, zinc, and tin, called gun metal, to the true shape at once, by means of an accurate pattern moulded in sand.

No. 14. The *drilling machine* is applied to perforate the three semicircular projections of the coaks; at the same time it drills through both the coaks and the wood of the sheave. The copper pins, which are put into these holes, are cut from the proper sized wire, by a simple tool fixed in the vice, all the same length. The pins being inserted into the holes, are carried to,

No. 15. The *rivetting hammers*, two small tilt hammers put in rapid motion by the machinery, for the purpose of rivetting the pins which hold the gun metal coaks into the cavity in the sheaves, made by the coaking engines. These hammers, also, by pressing on a treddle, can strike a heavier blow towards the end of the operation. The sheaves in this state are carried to,

No. 16. The *broaching engines*, of which three are used. The sheave is fixed to a vertical revolving axis, and the borer is brought down into the hole in the centre of the coaked sheave, and broaches it out to a perfect cylinder. The sheaves thus formed, require only to be turned in,

No. 17. The *face turning lathe*. This is an excellent lathe, provided with a sliding rest, which supports the turning tool, and moves it slowly across the face of the sheave, which is fixed upon the end of the spindle or mandrel of the lathe, and turned round thereby.

The blocks, shells, and sheaves, being now finished, we have to consider the iron pins for them. The small blocks, indeed, are fitted with pins of hard wood. The iron pins are first forged to the true size and shape, having a cylindrical part of sufficient length to pass through

the shell of the block; and a square part, which is to be drifted into one of the cheeks of the shell, to prevent the pin from turning round. They are then taken to,

No. 18. The *turning lathe*, where the iron pins are turned by a slide rest, in a manner something similar to the facing lathe: they are then covered with spiral scratches from the scoring of the tool. These are rounded by,

No. 19. The *polishing engine*. The pin is fixed into the lower end of a vertical revolving axis, and forced down into a sort of die, immersed in oil, holding three pieces of hard steel, between which the pin is pressed as it turns, and by that means is perfectly polished.

The wood pins are cut by the circular saw into octagonal pieces of the proper length. These are put into a common lathe, having adapted to it a simple tool, called a *witchit*, which quickly cuts the pin to a true cylinder, except a short piece at the end, which is left of an octagon form to be inserted into the cheek of the block, in order to prevent the pin from turning. We have not numbered this as a separate machine, because it is used in the common way of making blocks, being applied to the same lathe in which they turn the sheaves.

Besides all these machines, the block mills contain three others; one for large blocks, and two for dead eyes.

No. 20. The former is a complete *apparatus for boring very large holes* in any position. It is used for blocks of a size beyond what the regular machines are calculated for; some of these blocks being as large as 54 inches in length, with 4 sheaves. The shells for these are made up of pieces. They are used for the mast hulks; and by them the masts of the largest ships are suspended while they are fixed in their situation. The number of these blocks which is required, is not so great as to make it worth the expence of a set of machines for them; but the workmen avail themselves of all the assistance which they can derive from the largest of the three sets of machines, and perform the rest by hard labour. This large boring machine is the only one exclusively appropriated to large blocks.

No. 21. The *machines for making dead eyes*. After the scantling for these has been cut out by the machines before described, they are bored in the boring machine: The angles are then removed by the corner saw; and they are next put into a machine which shapes them, and cuts the score round them. They have two of these machines; the first making dead eyes from five to nine inches diameter, and the second being adapted to those from 10 to 19 inches.

Thus we have given a general idea of the objects of this really interesting mill; but a general idea of the whole is all that we can hope to give, from the limits we have been obliged to prescribe to our Plates. We shall select a few of the most curious of the machines, and give perspective drawings of them, reserving others for a future opportunity. On entering the block mill, the spectator is struck with the multiplicity of its movements, and the rapidity of its operations. The elegant structure of the small machines, strike the eye as objects of ornament as well as utility. On this score, great credit is due to Mr Maudsley for the perfection of workmanship displayed throughout these works; all the bearings, sliders, and fittings, being executed in the most accurate manner, so as to move freely, but without shaking. This accuracy is essential in these machines, as they are contrived so as to adapt themselves to blocks of

many different sizes and shapes; for if all the fittings were not very correct, the parts would be insufficient to restrain the large blocks, while they were clumsy and inconvenient for the small ones. This will appear from the great number of different blocks made at these mills, which are as follows:

Thick blocks, 4 varieties—single sheaves, double sheaves, treble, and fourfold. The sizes of each variety are from 4 inches to 28 inches in length; but only the three first varieties are wholly made by the machine; the fourfold, which are chiefly made with the hand, can only have the assistance of those machines which will form their parts: their sheaves and pins, however, are completely made by the machines.

These make about 72 sizes.

Thin blocks are the same, but with narrow sheaves: these run from 6 to 26 inches in length 48

Clue garnet and clue line blocks are of a peculiar construction, introduced by the inventor of the machinery. (See the article *Clue Block*) 10

It may therefore be safely said, that not less than 200 sorts and sizes of blocks are constantly making by these machines.

It will give some idea of the expedition of these works, to state the number of block shells of different sizes, made by each set of machines in a day.

The first set of machines make blocks from 4 to 7 inches in length, at the rate of 700 per day. These have wooden pins.

The second set from 8 to 10 inches in length, at the rate of 520 per day. These have iron pins.

The third set from 11 to 18 inches in length, at the rate of 200 per day, with iron pins. So that all the machines will make 1420 per day.

The larger sizes, from 19 to 28 inches, are not so frequently wanted as to employ the machines constantly: indeed they cannot make these large blocks by the machines alone, though they perform particular parts with them, as the sheaves, pin, and cheeks.

Having now enumerated the number and objects of these machines, we shall proceed to describe each of them in the same order.

The *straight cross cutting saw*. The log is placed horizontally on a very low bench, which is continued through the window of the mill into the yard. An horizontal shaft, turned by the mill, is situated over head, with a crank in it. The crank rod descends to the horizontal arm of a bent lever, whose centre is rather below the floor. The upper end of the vertical arm of this lever is jointed to the saw, which will therefore rise and fall on its joint in a vertical plane. It is a large pit saw without any frame, placed horizontally, its teeth downwards, but sloped so as to cut when drawn towards the lever. Over the back of the saw a piece of wood is fixed, and when the saw is lifted up upon the joint connected with the lever, so as to be at its most elevated position, the back of its blade is received into a kerf or cleft cut in this fixed piece of wood. The end of the

saw, opposite to that by which it is jointed to the lever, has a handle or spar fixed to it in a straight line with the blade : this spar, which may be called its handle, is received between two vertical posts, which confine it to move straight, but allow it to rise or fall. By a rope attached to this pole and conducted over a pulley, the attendant lifts up the saw into the cleft, in the fixed piece or guide before mentioned, (we suppose the saw is not now in motion, the crank being cast off from the mill,) then by a windlass and lever he draws the log forward on the platform, till the end of it (which we suppose has been cut off square by the same process we are about to describe) comes in contact with a lump of wood screwed upon the platform. The saw is now exactly over the place where the log is to be divided. It is let down and suffered to rest with its teeth upon the log, the back still being in the cleft of the guide. The crank being set in motion, the saw reciprocates backwards and forwards with exactly the same motion as if worked by a carpenter, and quickly cuts through the tree. When it first begins to cut, its back is in the cleft in the guide, and this causes it to move in a straight line; but before it gets out of the guide, it is so deep in the wood as to guide itself : for in cutting across the grain of the wood it has no tendency to be diverted from its true line by the irregular grain. When the saw has descended through the tree, its handle is caught in a fixed stop, to prevent its cutting the bench. The machine is cast off, the attendant lifts up the saw by the rope before mentioned, removes the block cut off, and advances the tree forwards to take a fresh cut. The lump of wood before mentioned can be fixed at any place along the platform, so as to cut any required length off the end of the tree. It should be mentioned, that a lever is placed across the end of the tree ; one end turning on a pin fixed in a firm post, and the other so loaded, as to keep the piece steady upon the bench when it is nearly or quite cut through. The under side of the lever is fitted with large teeth, which penetrate into the tree and hold it. This is a very simple and effective machine ; but does not cut so quickly as the circular saw which follows, because it does not admit of such a rapid motion ; but it can be constructed to cut trees of very large dimensions at a small expence.

The circular cross cutting saw. The reader must figure to himself a frame formed of two long parallel spars of wood, united by cross bars and braces ; this, which we call the saw frame, is suspended vertically by one end, where it is jointed to the end of a similar frame, (say the upper frame,) poised nearly horizontally, on an horizontal axis which passes through it near the middle of its length. The end opposite that which supports the saw frame is loaded, so as to counterpoise its weight. At the lower end of the saw frame, the spindle of the saw is mounted, by its bearings being bolted on the spars of the frame. The saw is fixed on the extreme end of the spindle, so as to be on the outside of the spars. The spindle is parallel to the axis of the upper frame. The tree is placed on a bench, and drawn up to a stop by a windlass, just the same as in the foregoing machine, and is kept steady by a crooked bar in a similar manner. The tree lies in a direction parallel to the axis of the saw. Now it will be seen by this arrangement, that the saw possesses universal motion ; but the axis is always parallel to itself, and the saw in the same plane. It can be raised up or lowered down, by inclining the upper frame on its axis ; and to move it sideways, the saw frame must swing sidewise on its joints,

which connect it with the upper frame. These movements are effected by two winches, each furnished with a pair of equal pinions, working a pair of racks fixed on two long poles. The spindles of these winches are fixed in two vertical posts, which support the axis of the upper frame. One of these pair of poles are jointed to the extreme end of the upper frame ; therefore by turning the handle belonging to them, the frame and saw is elevated or depressed : in like manner, the other pair are attached to the lower part of the saw frame, so that the saw can be moved sidewise by means of their handles, which then swing the saw from its vertical position.

These two handles give the attendant a complete command of the saw, which we suppose to be in rapid motion, the tree being brought forwards and properly fixed. By one handle, he draws the saw against one side of the tree, which is thus cut into, (perhaps half through ;) now, by the other handle, he raises the saw up, and by the first-mentioned handle he draws it across the top of the tree, and cuts it half through from the upper side ; he then depresses the saw and cuts half through from the next side ; and lastly a friiling cut of the saw, as the lower side completely divides the tree, which is then advanced to take another cut. The strap for the saw is conducted over pulleys, two of which are fixed on the upper frame near its horizontal axis ; and it then turns a pulley, fixed on an axis concentric with the joint, connecting the two large frames. On the same axis is another equal pulley, around which the strap is passed, which turns the pulley on the spindle of the saw. By this means, the strap never becomes slack in any movement of the saw, as its points of flexure are the same as the frames. This machine is very ingenious, and acts with great accuracy, and astonishing rapidity.

The *great reciprocating saw* is on the same principle as the saw mill in common use in America, at least the differences are so small, that they cannot be explained without drawings ; and as this machine is by no means essential to the manufacture of blocks, we shall refer our readers to the article *Sawing Machinery*.

The circular ripping saw, is a thin circular plate of steel, with teeth similar to those of a pit saw, formed in its periphery. It is fixed to a spindle placed horizontally, at a small distance beneath the surface of a bench or table, so that the saw projects through a crevice a few inches above the bench. The spindle being supported in proper collars, has a rapid rotatory motion communicated to it by a pulley on the opposite end, round which an endless strap is passed from a drum placed overhead in the mill. The block cut by the preceding machine, from the end of the tree, is placed with one of the sides flat upon the bench, and thus slides forward against the revolving saw, which cuts the wood with a rapidity incredible to any one who has not seen these or similar machines. The wood is guided in its progress toward the saw by a large parallel ruler, similar to that used for drawing, which can be placed and fixed at any required distance from the plane of the saw, but is always parallel to it : by this means the circular saw becomes a general machine, and can be adapted to cut any required width. Its great advantages are, the saving of labour, and the great accuracy of its performance, as it invariably cuts a perfectly plane surface ; and it is evident that any number of pieces cut by it must be of precisely the same size, when the parallel ruler remains fixed at the

same point. This is an important circumstance in these works, as the accurate performance of many, or indeed all the machines, depends upon the blocks which are submitted to them, at the same time, being of one size. We have not given these sawing machines among our Plates in this article, because this saw is in constant use for sawing in general, and will therefore come more properly under *Sawing Machinery*, where we propose to explain this, or a similar one constructed by Mr Maudslay, who has a peculiar mode of making the collars for the axis of the saw, which succeeds remarkably well. It is a great improvement upon the usual mode of fitting up the circular saw, and which, we believe, was first introduced (at least for sawing large timber) by Mr George Smart of London. In the old method, the ends of the spindle were perforated with small conical holes, and the conical points of two fixed screws were inserted into them. All the points of contact were made of steel, and hardened. Nothing could be more perfect or easy than the movement of such a spindle, until it was put into rapid motion by the machinery, when, having a considerable strain on the pivots from its work, it required a constant supply of oil, which was very quickly consumed, as the centrifugal force tended to draw the oil up the largest part of the cone, and consequently take it from the points of contact. If the machine continued to work without oil, the great velocity and pressure would cause such a friction, as to warm one or other of the steel joints. This would at once expand and soften it, so as to increase the friction in a two fold degree; and if this evil continued, the point would suddenly become red, or even white hot, and being too soft to resist the power of the saw, would then be twisted off. The broken point when cold, would then be found so jambed, or rather welded, into the hole in the end of the spindle, that it would be impossible to get it out except by drilling. The improved spindles, as constructed by Mr Maudslay, have double conical sockets, so disposed as to attract the oil into the fitting, instead of throwing it out. For small saws, where the strain is but slight, the old method is as good as can be devised. The blocks applied to the ripping saw are first split or ripped, in the direction of the grain, into the proper breadth in one direction, and then in the other, so as to reduce them to the proper scantling for the various sizes of blocks.

Boring machine. The blocks, prepared by the foregoing saws, are placed in the machine represented in Plate LVII. Fig. 4. This machine has an iron frame, AA, with three legs, beneath which the block is introduced, and the screw B being forced down upon it, confines it precisely in the proper spot to receive the borer, D and E. This spot is determined by a piece of metal fixed perpendicularly, just beneath the point of the borer E, shown separately on the ground at X: this piece of metal adjusts the position for the borer D, and its height is regulated by resting on the head of the screw α , which fastens the piece X down to the frame. The sides of the block are kept in a parallel position, by being applied against the heads of three screws tapped into the double leg of the frame A. These screws are represented by dotted lines in the Figure. The borer D is adapted to bore the hole for the centre pin in a direction exactly perpendicular to the surface resting against the three screws; the other, at E, perforates the holes for the commencement of the sheave holes. Both borers are constructed in nearly the same manner; they are

screwed upon the ends of small mandrels, mounted in frames similar to a lathe. These frames, G and H, are fitted, with sliders upon the angular edges of the flat broad bars, I and K. The former of these is screwed fast to the frame; the latter is fixed upon a frame of its own, moving on the centre screws, at L L, beneath the principal frame of the machine. By this means, the borer E can be moved within certain limits, so as to bore holes in different positions. These limits are determined by two screws, one of which is seen at a , the other being on the opposite side. They are tapped through fixed pieces projecting up from the frame. A projecting piece of metal, from the under side of the slider K of the borer E, stops against the ends of these screws, to limit the excursion of the borer. The frames for both borers are brought up towards the block by means of levers M and N. These are centered on a pin, at the opposite sides of the frame of the machine, and have oblong grooves through them which receive screw pins, fixed into the frames G and H beneath the pulleys P, P, which give motion to the spindles.

In using this machine, the workman draws back both borers, which always continue turning: He then takes the block and applies one of its sides against the heads of the three screws, resting it on the head of the screw α above mentioned, and thrusts it against the stop X. This ascertains the true position; and the screw B being screwed down upon it, holds it perfectly fast. The point of this screw has a steel ring, or washer, fitted upon it, the lower side of which is a sharp edge. When the screw is twirled round, the balls at the ends of its cross handle cause it to act as a fly-press, to stamp the impression upon the end of the block. The workman now takes the handles M, N, and forces them towards the block. This brings the borers against it; and, as they are in rapid motion, they will bore as fast as they can be followed up to the work. This is the process of boring a single sheave block, when the screw-stops at α are screwed so far as to confine the frame K in a vertical position, and then its borer makes a hole through the centre of the block. For a double block, the screws are withdrawn so far, that when the frame is held against one screw, its borer will be in the proper place for one hole; and, when inclined to the other screw, will be in the proper place for the other hole; and it is evident, that these limits, or the distance between the holes, may be increased or diminished at pleasure, to suit thick or thin blocks. The borers, which are made in the same form as a carpenter's centre bit, can be unscrewed, near the ends of their respective spindles, at b , to put on one of a larger or smaller size. The points of the screw-centers at L, upon which the frame of the borer E vibrates, can be put into different holes in the frame, so as to alter the difference of the level between the two borers, in order to suit blocks of different dimensions; and the screw α is changed for one with a thicker head, or, what is the same, a washer is put under its head. The stop X can be altered in its position, by sliding it farther from or nearer to the frame, and can be fastened by the screw α . Threefold blocks are bored at one operation, by the machine set in the same manner as for single blocks: They are then put in the machine when set for double blocks, and the two external holes bored.

The *mortising machine*, is exhibited in Plate LVIII. Fig. 4. which is a perspective view of this beautiful piece of mechanism. It is put in motion by an endless

strap passing round a drum at A, screwed to a fly-wheel B, that regulates the movement. This drum turns an axis D, on the extreme end of which is a crank. This has a long rod extending from it up to a joint at *a*, which connects it with a frame EE, fitted between sliders *b*, *d*, and guided by a cylindrical rod F, sliding through a fixed collar supported by the framing. By this means the frame is moved up and down when the axis D revolves. To this frame the chisels are fastened, and operate upon the block fixed at G, in a carriage H, sliding horizontally in the frame of the machine. *e*, *e*, *e*, are three screws, the same size as the screw of the boring machine, and each furnished with the same sized ring at its end. This enters the impression made by the boring machine, so as to fix the block in its proper position when the screw is turned. This forces the other end of the block against a cross bar of the carriage, shewn separately on the ground at Y. It has three steel circles, or rings, *f*, fixed to it opposite the ends of the screw *e*. Each of these rings includes two smaller rings, also made with a sharp edge. Now the pressure of the screw *e* forces the block against these rings, so as to print their impression in the wood; and by this means the block is held quite fast in the carriage while undergoing the process of mortising. The carriage has a large double wormed screw R attached to it behind, and this is received through a nut, or female screw, which is fitted to turn round in a fixed collar, supported by a bar extended across the frame of the machine. To this nut two wheels *g*, *h*, are fixed; the former is a large ratchet wheel, the latter a cog wheel, which has a smaller one gearing with it. This is fixed on the end of a long axis *k*, on the extremity of which is a winch *r*. When this is turned round by the attendant, the nut of the screw is turned at the same time, and the carriage moved slowly, either backwards or forwards. This motion is only intended to adjust the carriage to the proper point of commencement. The gradual advancement of the block to each cut of the chisel, is produced by turning the ratchet wheel *g* in this manner:—The axis D has an eccentric circle I fixed upon it; which, as it revolves, acts upon a roller K, fixed in one arm of a bent lever, which cannot be wholly seen in the view: the other end of this arm has a rod *m* jointed to it, having a tooth in the middle, which engages the teeth of the ratchet wheel, and turns it round a tooth at a time, as the rod reciprocates backwards and forwards. The extreme end of this rod rests upon a lever *n*, (except when it rises up by being drawn over the sloping side of the tooth of the ratchet wheel,) the centre of which is a pin fixed in the vertical column of the frame. It is held up by a second lever *o*, supported on a cock screwed on the frame. The opposite end of this lever is made so thick and heavy, that the weight of it is sufficient to raise up *n* and *m*, so that the tooth of the latter will be too high to intercept the teeth of the ratchet wheel in its motion. The heavy end of the lever is kept up by a piece of metal fastened to the side of the carriage at *p*. The screws which fasten this, pass through oblong grooves in it, so that it can be fixed at different parts along the length of the carriage. By this means when the carriage has advanced as far as intended, the loaded end of the lever *o* falls off the piece *p*, and disengages the rod *m* from the ratchet wheel. The fly-wheel and drum which turns the machine, are, as before mentioned, screwed together; but they are fitted on a cylindrical part of the axis, so as to turn freely thereon,

when it is not required to turn the axis D, and work the machine. A conical wheel S, having a hollow axis or tube centre piece, is fitted upon the axis D, so as to slide freely endwise, but is confined to revolve at the same time by fillets inserted into it. The end of the tube of the wheel S is formed into a circular groove, which is embraced by a forked lever L, centered in the opposite side of the frame. Now by moving the end of L towards the fly-wheel, the conical wheel S is thrust forwards, and jammed into the inside of the drum A. This exactly fits the wheel; and the friction caused by the contact of the two conical surfaces, is sufficient to work the machine. On the other hand, when the lever L is pulled away from the fly-wheel, the conical wheel is drawn out from the rigger, and by that means the fly-wheel is detached from the axis, so as to revolve upon it freely without turning it; but, to prevent any danger of the axis being turned by the friction of the fly-wheel upon it, the wheel S has another cone formed on the back of its rim, the bases of the two being conjoined. When the wheel is drawn back, this cone is jammed into a fixed ring M, supported by the frame of the machine, so as to be fixed fast, and prevent the axis from turning.

The mortising machine is used in the following manner: The block brought from the boring machine has the print formed by the screw thereof applied to the end of one of the screws at *ee*. If one double or three-fold sheave block is to be mortised, as shewn in the Figure, the centre screw alone is used to hold it in; but if two single sheaves are to be fixed in, then only the outside screws are used, the centre one being left loose. By screwing it tight, the block is fixed between the double circle prints, before mentioned, on the bar Y; and stops are situated on the same bar. To guide the block to its proper position, which is, that the hole bored for the commencement of the sheave hole shall be vertical, suppose the block fixed, the handle *r* is turned till the hole is brought beneath the sliding frame. The chisels are now adjusted. These are long square bars of steel TT, and are fastened to the frame by a clamp, seen separately at X. This goes behind the cross bar of the frame, and has two square holes through its ends, to receive the chisel T, and two screws to bite it fast in the square holes; at the same time that this keeps the chisels from slipping up and down, it fixes them fast to the frame EE, by drawing the chisels forcibly against the cross bars, by means of the clamps behind them. The two screws of each clamp being slackened, the chisels are put exactly over the holes which are to become sheave holes, and screwed fast. The machine is now put in motion by depressing the handle P. This is at the end of a lever, the fulcrum of which is a pin fixed in the column of the frame at *s*; and a short arm gives action to the end of the lever L, before described, so as to put the machine in motion. At the first descent of the chisels, they cut down through the whole depth of the holes previously bored, so as to give them a flat side when they rise up. The eccentric circle I, moving the bent lever and rod *m*, turns the ratchet wheel round on both, and advances the block a very minute quantity from the fly wheel; so that the chisels in descending cut a fresh space, and in ascending the block advances. In this manner it proceeds, with a most astonishing rapidity, through the whole length of the intended sheave hole. At this time the loaded end of the lever *o* drops off the piece *p*, previously adjusted.

and raises the rod *m*, so that the farther advance of the block is prevented. When the boy who attends the machine observes this, he raises the handle *P*. This stops the machine, as before stated; and the boy takes care to stop it when the chisels are at the highest point, which he effects by a very dextrous movement. The finished block is now removed, and a fresh one put in; the handle *r* is screwed back, to bring the block to the proper point, and the machine starts, and proceeds as before.

The backs of the chisels have a small piece of steel *r* fixed to them, which thrusts out the chips which they cut, otherwise these would accumulate and wedge up the hole, so as to obstruct the chisel most materially, by filling up the space behind it. It has also two small cutters, called scribers, at *vv*, fixed perpendicular to its edge, so as to project rather before it, being fitted in dovetail notches, formed in the sides of the chisels. These small scribers, in the descent of the chisel, cut or scribe two small clefts, which include the width of the chip which will be cut out by the chisel in the succeeding stroke. By this ingenious device, the mortise cut in this machine has its sides as smooth as if they were made by a plane. The back of the chisel is rounded, to conform to the hole bored in the boring machine.

To adapt the mortising machine for different sized blocks, the cross bar *Y*, in the back of the carriage, against which the blocks are pressed, can be fixed by notches cut in the frame, at one inch assunder, so as to hold all blocks of different lengths, having an inch difference in each. The stops, above mentioned, to ascertain the position of the block, can be fixed upon the cross bar at any point, either as to height or position sidewise, in the following manner: The piece of iron *vv*, (see the separate view,) with a groove through it, carries two vertical pieces *xx*, at the upper and lower end of which is a knob; these will place the sides of the blocks applied against them truly vertical. Two small pillars *nn* are fixed to the cross bar of the carriage; they have a piece sliding upon them, which can be fixed at any height by screws, to adapt it for different sized blocks. The two pieces *xx*, are fixed at the same distance asunder as the screws in the front of the carriage; so that when one is set in the position for a block, to be held by one screw, the other will be at the proper place for the other screw: by these means the carriage can be adapted to receive a block of any dimensions, and can guide it to its proper position against the prints in the cross bar. The frame *E* may have any number of chisels fixed to it, corresponding to the number of mortises intended to be cut.

The *corner saw* (see Fig. 5. of Plate LVII.) consists of a mandrel mounted in a frame *A*, and carrying a circular saw *L*, upon the extreme end of it. This mandrel and its frame being exactly similar to those at *G* and *H*, Fig. 4. Plate LVII. does not require a separate view, although it is hid behind the saw, except the end of the screw marked *A*. This frame is screwed down upon the frame *BB* of the machine, which is supported upon four columns. *CC*, *DD* is an inclined bench, or a kind of trough, in which a block is laid, as at *E*, being supported on its edge by the plane *CC* of this bench, and its end kept up to its position by the other part of the bench *DD*. By sliding the block along this bench, it is applied to the saw, which cuts off its angles, as is evident from the Figure, and prepares it for the shaping en-

gine. All the four angles are cut off in succession, by applying its different sides to the trough or bench. In the figure, two of them are drawn as being cut, and the third is just marked by the saw. This machine is readily adapted to different sizes of blocks, by the simple expedient of laying pieces of wood of different thickness against the plane *DD*, so as to fill it up, and keep the block nearer to or farther from the saw; for all the blocks are required to be cut at the same angle, though, of course, a larger piece is to be cut from large than from small blocks. The block reduced to the state of *E* is now taken to

The *shaping machine*, represented in Plate LIX. as it is seen from one side. A great deal of the apparent complication of this figure arises from the iron cage which is provided to defend the workman, lest the blocks, which are revolving in the circles, or chuck, with an immense velocity, should be loosened by the action of the tool, and fly out by their centrifugal force. Without this provision, the consequences of such an accident would be dreadful, as the blocks would be projected in all directions with an inconceivable force. The principal part of this machine is its chuck, which holds the blocks. This consists of two equal wheels *AA* and *BB*, placed upon the same axis, the former of which is firmly fixed to the axis, while the latter slides upon it, in order to render the space between them greater or less, as is required, to contain blocks of different lengths. This is effected by five bolts, fixed into the rim of one wheel, and passing through the rim of the other. Each bolt has a nut upon it on the outside of the wheel *B*. By means of these nuts the wheel *B* is held fast at any required distance from the other. The head of some of these bolts are marked *x*. Both wheels of the chuck are divided into ten equal parts. At each of these joints, on the wheel *A*, a short axis, or mandrel, is fitted through a projecting part of the rim of the wheel. On the outside of the wheel, each of these mandrels has a small wheel *a* fixed upon its end. On the ends, in the inside of the wheel, the mandrels have each a short cross bar fixed, just sufficiently long to contain two steel rings; which are exactly the same size and distance apart as those in the mortising machine, which support the block. The wheel *B* has, at each point opposite the mandrels *a*, a screw centre similar to the back centre of a lathe, but furnished at its point with a steel ring, of the same dimensions as that at the end of the screw of the boring machine. The ring is fitted upon the point of the screw, to turn freely upon the end of it. The blocks are held in between the wheels, by putting the double print at one end of each block against the double rings at the end of one of the mandrels, and then screwing the screw in the other wheel tight up, the block is confined between them. In this manner, the chuck being filled with ten blocks, if they are turned round rapidly, and a chisel or gouge fixed for them to cut against, each will be formed to a segment of the circle in which they move. This gouge is supported in a frame, moving on a fixed rest *D*, which is curved to a circle, whose centre is in the centre of the chuck. It is confined to move on this arch by a curved radial bar *E*, fitted to centre on the floor beneath the machine at one end; and having the other attached to the frame *FF*, which supports the tool. This frame contains a slider *f*, moving in a groove, and at the end carrying the tool *g* in a holder, where it is fixed by a screw. The slider has an axis or spindle, fitted perpendicularly in

it at *h*. On the lower end of this is a roller, which applies itself against a curved piece of metal *i*, called a shape. It is fixed fast upon the framing of the machine by a pillar at each end. The roller is kept in contact with the shape by a lever, centered at *k* on the frame *F*, and connected by a short coupling iron with the slider *f*; so that, when its handle *l* is pressed towards the machine, the roller is kept up to the shape. *G* is a handle jointed to the frame *F*; and, by means of this, the frame *F*, carrying the tool and all its apparatus, can be moved along the rest *D*, being guided by the radial bar *E* in its motion. It is evident, that if the other handle *l* is at the same time pushed forward, the roller applies itself to the shape, and, consequently, the gouge describes the same curvature that the shape has. This curvature can readily be altered by the following means: There is a second shape *m* fixed below the former, and, by a simple movement, the roller can be depressed, by slipping its axis downwards in its socket, so as to roll along the lower shape, and give the curvature of it to the tool, instead of the upper one.

The mode of using this machine is as follows: The ten blocks being all fixed in, as before described, and as shown in the Figure, the frame *F* of the gouge is turned to one end of the rest *D*, and the chuck put in rapid motion by a band round a pulley *H*, fixed on its axis. The workman, with the handle *G* in his right hand, and *l* in his left, sweeps the frame along its rest with the handle *G*, while he keeps the roller in contact with the shape, by pressing the lever *l* towards the machine. In this movement the gouge cuts all the ten blocks at once to their proper curvature, at least that face of each which is farthest from the centre. When the frame has slowly traversed the whole length of its sweep, the outside face of all the blocks are finished, and the machine is stopped by casting its movement off from the mill: But, as it preserves a considerable momentum, this is checked by a steel spring at *l*, which is fixed at one end to the frame, and then extends round a wheel fixed on the pulley *H*, or rather cast in the same piece. The other end of this spring has a handle upon it; and when this is pressed down, the curved part of the spring incloses the wheel, and operates as a gripe, to check the velocity of the chuck. When the motion ceases, the blocks are all turned one quarter round on the small mandrels *a* by this means. The wheels *a* have each an endless screw, which turns them round. These screws are cut in the ends of as many spindles *d*, pointing towards the centre of the chuck. At the ends of these, nearest the centre, each spindle has a small bevelled wheel *e* fixed upon it. There is also a large bevelled wheel *K*, which is fitted upon the axis between the wheel *A* and the pulley *H*, so as to slip freely round upon the axis, and when it is turned round, it is evident it will turn all the wheels, spindles, screws, and mandrels, at once, and by that means turn all the blocks, so as to bring another face outwards. This is not effected by turning the wheel; but, what has the same effect, the wheel is held fast while the chucks are turned round. To stop the wheel *K*, a catch *L* is employed. It moves on a joint fixed on the ground; and when pushed towards the wheel, a stub, or knob, projecting from its rim, is caught in a fork, or notch, at the upper end of the catch. The wheel is now detained, and the attendant to the machine takes hold of the chuck by its rim, and turns it round four times, which he determines by a mark on the wheel *A*. The bevelled and other wheels

are so proportioned, that these four times will make the blocks revolve exactly one quarter on their individual axes, so as to bring another side of each outside. This being done, the catch *L* is removed, the roller at *h* is shifted by depressing its axis; so that its roller acts against the lower shape, which has a curvature suiting the other side of the blocks. The machine is now put in motion, and the tool moved along its rest, in the same manner as before described; forming, in this manner, the second side of each block. The machine is now stopped, the blocks turned round another quarter, and the upper shape is employed to cut the third side, in the same manner as the first; which being done, the fourth side is cut in the same manner as the second, and with the same shape. The blocks are now completely shaped, and the ten are removed to make way for another set, which are treated in the same manner.

The roller *h*, or rather the socket supporting its axis, is not fixed to the slider *f*, but is litted to the same in a groove; so that, by means of a screw *n*, it can be moved along the slider. The effect of this is, that the tool *g* projects more or less beyond the shape, as is required to cut larger or smaller blocks. The mode of adapting the chuck to take in larger blocks has been before mentioned. The same shapes will serve several different sizes; and if not, they can easily be removed, and others substituted of the proper curvature.

The *scoring engine* receives two blocks, as they come from the shaping engine, and forms the groove round their longest diameters, for the reception of their ropes or straps. *A*, *B*, (Fig. 1. Plate LX.) represent these two blocks, each held between two small pillars, *a*, (the other pillar is hid behind the block,) fixed in a strong plate *D*, and pressed against the pillars by a screw *b*, which acts on a clamp *d*. Over the blocks a pair of circular planes or cutters *EE* are situated, both being fixed on the same spindle, which is turned by a pulley in the middle of it. The spindle is fitted in a frame *FF*, moving in centres at *ee*, so as to rise and fall, when moved, by a handle *f*. This brings the cutters down upon the blocks; and the depth to which they can cut, is regulated by a curved shape *g*, fixed by screws upon the plate *D*, between the blocks. Upon this rests a curved piece of metal *h*, fixed to the frame *F*, and inclosing, but not touching the pulley. To admit the cutters to traverse the whole length of the blocks, the plate *d*, (or rather a frame beneath it,) is sustained between the points of two centres. Screws are seen at *l* on these centres. The frame inclines when the handle *L* is depressed. At *M* is a lever, with a weight at the end of it, counterbalancing the weight of the blocks and plate *D*, all which are above the centre on which they move. The frame *F* is also provided with a counterpoise to balance the cutters, &c. The cutters *E*, *E* are circular wheels of brass, with round edges. Each has two notches in its circumference, at opposite sides; and in these notches chisels are fixed by screws, to project beyond the rim of the wheel, in the manner of a plane iron before its face.

This machine is used as follows: In order to fix the block, it is pressed between the two pins, (only one of which at *a*, can be seen in view), and the clamp *d* screwed up against it, so as just to hold the block, but no more. The clamp has two claws, as is seen in the Figure, each furnished with a ring, entering the double prints before mentioned, in the end of the block. These rings are partly cut away, leaving only such a segment of each

BLOCK MACHINERY.

as will just retain the block, and the metal between them is taken out to admit the cutter to operate between them, or nearly so. In putting the blocks into this machine, the workman applies the double prints to the ends of the claws of the clamps, but takes care that the blocks are higher up between the pins *a* than they should be; he then takes the handle *f*, and by it presses the cutters *EE*, (which we suppose are standing still,) down upon the blocks, depressing them between their pins at the same time, till the descent of the cutters is stopped by the piece *h* resting on the shape *g*. He now turns the screws *bb*, to fix the blocks tight. The cutters being put in motion, cut the scores, which will be plainly seen by the mode of adjustment just described, to be of no depth at the pin hole; but by depressing the handle *L*, so as to incline the blocks, and keeping the cutters down upon their shape *g* by the handle *f*, they will cut any depth towards the ends of the blocks, which the shape *g* admits.

By this means, one quarter of the score is formed; the other is done by turning both blocks together half round, in this manner: The centres *l* are not fitted into the plate *D* itself, but into a frame seen at *R*, beneath the plate, which is connected with it by a centre pin, exactly midway between the two blocks *A, B*. A spring catch, the end of which is seen at *r*, confines them together; when this catch is pressed back, the plate *D* can be turned about upon its centre pin, so as to change the blocks, end for end, and bring the unscored quarters (*i. e.* over the clamps) beneath the cutters; the workman taking the handles *f* and *L*, one in each end, and pressing them down, cuts out the second quarter. This might have been effected by simply lifting up the handle *L*; but in that case the cutter would have struck against the grain of the wood, so as to cut rather roughly; but by this ingenious device, of reversing the blocks, it always cuts clean and smooth, in the direction of the grain. The third and fourth quarters of the score are cut, by turning the other sides of the blocks upwards, and repeating the above operation. The shape *g* can be removed and another put in its place, for different sizes and curves of blocks; but the same pins *a*, and holding clamps *d*, will suit many different sizes.

By these machines the shells of the blocks are completely formed, and they are next polished and finished by hand labour; but as this is performed by tools and methods which are well known, it is needless to enter into any explanation: the finishing required being only a smoothing of the surfaces. The machines cut so perfectly true, as to require no wood to be removed in the finishing; but as they cut without regard to the irregularity of the grain, knots, &c. it happens that many parts are not so smooth as might be wished, and for this purpose manual labour alone can be employed.

The *lignum vitæ* for the sheaves of the blocks, is cut across the grain of the wood by two cross cutting saws, a circular and straight saw, as before mentioned. These machines do not essentially differ in their principle from the great cross cutting saws we have described, except that the wood revolves while it is cutting, so that a small saw will reach the centre of a large tree, and at the same time cut it truly flat. As the limits prescribed our Plates will not admit of giving drawings of these machines, and as the idea which could be derived from a verbal description would not be materially different from the cross cutting saws before mentioned, we shall defer any farther account of them till a future opportu-

nity. These machines cut off their plates for the end of the tree, which are exactly the thickness for the intended sheave. These pieces are of an irregular figure, and must be rounded and centered in the crown saw.

The *crown saw* is represented in Plate *LX*, Fig 2, where *A* is a pulley revolving by means of an endless strap. It has the crown or trepan saw *a* fixed to it, by a screw cut within the piece, upon which the saw is fixed, and which gives the ring or hoop of the saw sufficient stability to perform its office. Both the pulley and saw revolve together upon a truly cylindrical tube *b*, which is stationary, being attached by a flaunch *c* to a fixed puppet *B*, and on this tube as an axis, the saw and pulley turn, and may be slid endwise by a collar fitted round the centre piece of the pulley, and having two iron rods (only one of which can be seen at *d* in the figure,) passing through holes made through the flaunch and puppet *B*. When the saw is drawn back upon its central tube, the end of the latter projects beyond the teeth of the saw. It is by means of this fixed ring or tube within the saw, that the piece of wood *e* is supported during the operation of sawing, being pressed forcibly against it by a screw *D*, acting through a puppet fixed to the frame of the machine. At the end of this screw, is a cup or bason which applies itself to the piece of wood, so as to form a kind of vice, one side being the end of the fixed tube, the other the cup at the end of the screw *D*. Within the tube *b*, is a collar for supporting a central axis, which is perfectly cylindrical. The other end of this axis (seen at *f*) turns in a collar of the fixed puppet *E*. The central axis has a pulley *F*, fixed on it, and giving it motion by a strap similar to the other. Close to the latter pulley a collar *g* is fitted on the centre piece of the pulley, so as to slip round freely, but at the same time confined to move endwise with the pulley and its axis. This collar receives the ends of the two iron rods *d*. The opposite ends of these rods are, as above mentioned, connected by a similar collar with the pulley *A* of the saw *a*. By this connection, both the drill, which is screwed into the end of the central axis *f*, and the saw sliding upon the fixed tube *b*, are brought forward to the wood at the same time, both being in rapid motion by their respective pulleys. The power to bring them forward is communicated to the machine by a bent lever *H*, having a handle *h* at the end, and at the other end a fork, which receives the two ears or pins projecting from a collar *i*, fitted on the central axis, so that the rotatory motion is not interrupted; but the collar cannot slip endwise upon the spindle. At *k* is a spring of sufficient strength to counterbalance the weight of the handle, and draw both the saw and centre bit back. In this state, the workman takes a piece of wood and places it against the end of the fixed tube *b*, so as to be nearly concentric with the saw; then by turning the screw *D*, he advances the cup at the end of that screw, so as to hold the wood fast; this being done, he depresses the handle *h*, and, as above described, brings the centre bit and the saw both together against the wood. The former bores the central hole, while the latter cuts out the circular periphery of the intended sheave: then raising the handle *h*, the saw and borer retreat, and the round piece of wood may be removed to make way for another rough scantling.

This machine is easily adapted to cut sheaves of different dimensions, by unscrewing the saw from the centre piece of its pulley *A*, and putting on a larger or smaller one; and the same is the case with the centre

bit, which is attached to the central axis, by screwing into the end of it.

The coaking engine. This ingenious piece of machinery is represented in Plate LXI. Fig. 1. It is used to cut the three semicircular holes which surround the hole bored by the crown saw, so as to produce a cavity of the shape represented in the sheave S lying on the ground beneath the machine. To effect this, the sheave is fixed (by an universal chuck entering its centre hole) to a circle A, which has three arms extending from it. This circle has a short axis passing through a lever BC, of which C is the fulcrum, formed by a pin projecting from the frame of the machine. D, E, F are three columns rising from the circular frame G. These sustain an upper frame, and two vertical rods *a*. Upon these, a frame slides, carrying a small mandrel *b*, which has the cutter fixed at its lower end. The sliding frame has a screw at *d*, which prevents its descending too deep into the sheave; and a catch at H retains it when raised up above a certain height, so as to hold it out of the way while the sheave is fitting in. The lever BC has a motion on its centre within certain limits, which are determined by two screws, one at *e*, and the other unseen, intercepting the end of a bolt *f*, fitted to the underside of the lever; but by withdrawing this bolt, the lever may be brought forward, so as to remove the sheave to some distance from the centre of the circular frame.

The circle A is confined from turning round on its axis, by the end of one of its arms being engaged with the hook of a detent *h*, which is pressed towards the centre of the wheel by a spring. When this detent is withdrawn by the finger, the circle A may be turned round till the next arm comes to the detent, when it is locked till again set at liberty by the finger. The universal chuck formerly mentioned, for fixing the sheave to the circle A, is an admirable contrivance. The centre piece expands itself concentrically with the axis, in order to fill the centre hole of the sheave in the following manner. A pin is fitted through the centre of the axis of the wheel A, made cylindrical in the part where it fits the axis, but with a fillet to prevent it from turning round. At the lower end it is tapped, and has a nut *r* fitted upon it. The upper end above the axis is formed conical, the smallest part being downwards. Round this is fitted a small ring of steel, the inside conical to fit the pin, and the outside cylindrical, the size of the inside of the centre hole of the sheave. This steel ring is divided into three segments, kept together by a piece of watch spring lapped round them, and contained in a groove turned round the outside of the ring, so that the spring is lodged beneath the surface of the outside of the three segments of the ring. When the nut *r* is screwed down, and the pin pushed up, the spring surrounding the steel ring collapses the segments upon the smallest part of the cone, so that the chuck is of its smallest dimensions. One of the pieces of wood, rounded and centered in the crown saw, is now put with its central hole over the chuck. The nut *r* being screwed, draws the pin down, and the conical head of it expands the steel ring, so as to jam fast in the central hole, and fix the sheave upon the wheel A. This being done, the lever B is pushed as far as it will go towards the cutter; and the spindle *b*, with its frame, being let down, by disengaging the hook H, its cutter enters the centre hole, (we suppose it all the while revolving by its band,) and the lever B being drawn towards the spectator, it cuts a semicircle of its own diameter on one side of the

centre hole, till the lever B is stopped by the point of the screw at *v*. The lever is now pushed back to rest upon its opposite screw, the detent *h* is withdrawn, and the wheel turned round by one of its arms, till a succeeding arm engages the tooth of the detent; then the lever is drawn down towards the spectator, and cuts the second semicircle at 60 degrees distant from the former. This being done, the lever is brought forward, the circle turned round, and the third hole cut. It must be noticed, that when the sheave is turned round with the circle A, the cutter still cuts a part of the wood, and acts to enlarge the central hole to the proper figure, to contain the metal coak or centre. One side of the sheave being cut in this manner, the nut of the screw *r* is slackened, the sheave taken off, and turned the other side upwards, which is to undergo the same process. The semicircles on the different sides of the sheave are cut exactly opposite, by means of a small cylindrical pin, with a head large enough to fill one of the semicircles. At the proper distance from the centre, this pin is countermarked in the circle A, and has a small spiral spring surrounding its tail, which throws it always upwards. While the first side of the sheave is cutting, this pin is pressed into the circle, level with its surface; but when the second side is to be done, the sheave, while fixed to the circle, is turned about on its centre pin, till the pin jumps up into the first semicircle which comes over it, and locks the sheave from turning round farther. The screw *r* is now lightened to fix the sheave fast; and in this position the sheave is ready for cutting, and the semicircles will be exactly opposite each other. The cutters unscrew from the end of the spindle, to change for different sizes, and this regulates the diameter of the semicircle. Its distance from the centre of the sheave can be increased or diminished by the screw opposite to *e*. The quantity which the centre hole will be enlarged, is determined by the screw at *c*; and the depth which the semicircle will be cut, is gauged by the screw *d*. And, lastly, the universal chuck can be changed for one larger or smaller, by removing the nut *r*, and putting in a fresh one. By these means, this engine will suit many different sizes of sheaves. The sheaves thus prepared, have the coaks fitted into them. These are cast in gun metal of the true size, to fill the cavity cut by the coaking engine. Each sheave has two coaks, one shewn at L, below Fig. 1. Plate LXI. and the other at M. The former has a barrel or tube *w* projecting from it, which passes through the central hole of the sheave; but M is only a ring put in on the opposite side, and receives the end of the barrel, which is rivetted down in it, so as to hold both fast in their places. But besides this rivetting, three pins are put through both coaks and the sheaves, and rivetted fast. One of these pins passes through the centre of each semicircular projection of the coak. These pins are made of copper wire, from a coil of which they are cut by a small pair of shears held in the vice, and provided with a stop behind them, which regulates the length of the pins.

The coaks being inserted into the sheave, are taken to the drilling machine. Here a drill is in constant motion. The workman applies a sheave against it, and quickly drills through both the coaks, and also through that part of the wood of the sheave which is between them. The place where the hole is to be drilled is pointed out by a small dent in the casting of the coak, in the centre of each semicircle. Into these holes the

pins above mentioned are inserted, and the sheave is taken to the rivetting hammer.

This is a small hammer mounted on an axis, so as to move up and down. The tail of the hammer projects beyond the axis, and is pressed down at intervals by three cogs fixed into a small wheel, revolving by the machinery. By pressing the tail, these raise the head of the hammer, and it falls partly by its own weight, and from being assisted by a strong spring which presses upwards beneath the tail, and throws the hammer down. This spring is fixed on a lever, the end of which rests upon an eccentric wheel, which can be turned round by a rope, connecting it with a treadle placed beneath the machine. When the workman presses his foot upon this treadle, it turns the eccentric wheel, and raises up the lever, so as to strengthen the spring, and throw the hammer down with greater force. The workman holds the sheave upon the anvil, and the hammer strikes upon the pins and coaks so as to beat them down, and rivet them fast in their places. At first the hammer strikes lightly; but as the process goes on, the workman presses his foot on the treadle, which strengthens the spring, and makes the hammer strike more forcibly towards the end of the rivetting.

The coaks being thus fixed fast in their places, are broached out to render the centre hole through them truly cylindrical. For this purpose, the sheave is placed upon a flat chuck at the upper end of a vertical mandrel, which we suppose standing still, though it is capable of being turned round by the mill. A broach, or cutter, is brought down into the hole, to enlarge it to the true figure. The sheave is fixed truly concentric with the mandrel, by the end of the broach, which is cylindrical, and is not, therefore, the cutting part, being received into a hole in the end of the mandrel, which it exactly fits. This insures the broach and spindle being in one line; and as the cylinder part of the broach fills the hole through the coak, it fixes the sheave on the centre of the chuck. A clamp is now brought down upon the sheave, one end moving on a hinge fixed to the chuck, and the other forced down by a screw; this clamp fixes the sheave on the chuck, and the machine is put in motion. The sheave with its mandrel are now turning round, and the broach is brought lower down into the end of the mandrel, so that the cutting part comes against the metal of the coak, and enlarges the hole sufficiently to make it perfectly true and smooth. The cutting part of the broach is a steel cutter, or tooth, fixed into one side of the cylindrical part of it. The inside of the hole through the coaks have spiral grooves made round in them in the casting, and these are too deep to be removed by the broaching. They are intended as receptacles for grease, which is a very necessary precaution, as blocks, when in use, cannot often be greased. The sheaves are now finished except the turning of the groove in their edges. This is done in the

Face turning lathe. (See Fig. 2. of Plate LXI.) The sheave A is fixed against a flat chuck at the end of a mandrel B, by an universal chuck, similar to that before described in the coaking engine, except that the centre pin, instead of having a nut, is tapped into the flat chuck and turned by a screw-driver. The sheave turns in such a direction, that the action of the work tends to screw it faster. By this means the slightest force is sufficient; even turning the screw by the thumb nail will expand the chuck sufficiently to turn the sheave

round, and the drift of the work will fix it perfectly fast. The mandrel B is turned round by an endless strap X, working on either of the drums D or E; the former of these is fixed to the mandrel, and the latter is fitted upon it to slip round freely. Now when the strap is working on the loose pulley E, as in the figure, it slips upon the mandrel, and the machine stands still; but by moving the strap upon the other pulley, it turns the machine round. The tool *a*, for turning the sheave, is fixed in a slide rest, being held by a screw *b*. This attaches it to a dove-tailed slider *d*, which will move in a groove, on an assemblage of pieces marked F, in a direction perpendicular to the mandrel. The groove F of this slider is fitted to slide upon a parallel dove-tailed piece G, fixed down upon the frame of the machine. Both sliders are moved by screws. That which moves the lower slider F, is turned by a small winch handle at Y. When turned, it advances the upper slider with its screw, the tool, and all the apparatus towards the sheave, fixed at the end of the mandrel. The screw of *d* has a pulley H placed on the end of it, but fitted to slip round, and *e* is an arm, fitted on the end of the screw, to slide to and from the pulley, but made with a fillet, so that it must always turn round with the screw. The central piece of the arm *e* has a groove round it, which is embraced by an opening in the middle of a lever *f*, exactly the same as the lever in the mortising machine. One end of this lever is jointed to the solid piece F, and this is its fulcrum; the opposite end, marked *f*, is jointed to a rod *g*, suspended in an iron loop *h*, fixed at its upper end to the holder for the tool *a*. By moving the rod *g* endwise, the arm *e* slides upon its spindle, and, when pushed towards the wheel H, intercepts a stub projecting from the wheel, which is always turning, and now carries the screw with it; but when the arm is pulled away from the wheel, the connection is destroyed, and the pulley slips round on its spindle, which is the end of the screw. The wheel H is turned round by means of an endless band passing round a pulley *k* on the end of a spindle, carrying the wheel *h*, which is turned by an endless screw upon the mandrel at l. The band passes over the pulley *k*, then makes a turn round H, and goes to a pulley K, from which it returns to *k*. The pulley K is situated at the end of a spring M, fixed to a pillar of the frame. The elasticity of this spring is such as to cause a sufficient tension of the band to turn the wheel round, and the direction of the band allows the position of the pulley H to be altered, by turning the screw Y, without loosening or tightening it. N is a rest, similar to that used in a common lathe, fastened by a screw passing down through the frame. The workman takes a sheave, and fixes it against the chuck at the end of the mandrel B, fastening it tight by the screw in the centre; then by pressing the strap X sidewise, it passes on the pulley D, and puts the mandrel in motion. The screw Y is now turned, till the tool at *a* advances so as just to cut the coak of the revolving sheave, (we suppose the screw of the slider *d* has been previously withdrawn, by turning back the handle O, so as to bring the tool nearly into the centre of the sheave.) The workman now pushes the rod *g* towards the pulley H: this, as before described, puts the screw in motion, and moves the slider *d*, with the tool, away from the centre of the sheave, turning it all the way across to a true flat surface. When the tool arrives at the outside of the sheave, the loop *h*, which moves at the same time, intercepts a nut *n*, screwed on the end of the rod *g*, and by this means

draws the rod, relieving the arm *c* from the pulley *H*, so that the motion cannot be continued to break or damage the screw or sliders. During the time the tool was traversing the face of the sheave, the attendant, having nothing else to do, was employed in turning the groove in the edge of a sheave, by a gouge placed on the rest *N*. The lathe is now stopped, by shifting the strap *X* upon the loose pulley *E*. The sheave is removed from its chuck, and turned with the other side towards it. Then the handle *Y* is turned back, to draw the tool *a* clear away from the sheave, and the handle *O* is turned back to bring the tool again to the centre. The lathe is now set in motion, and the operation above described repeated, except that the groove on the edge does not require to be turned a second time. In our drawing, we have not been able to explain a most ingenious contrivance in the pulley, which gives motion to the endless strap turning the lathe. It is found by experience, that a certain velocity is best for turning brass or other soft metals to the greatest advantage, or of cutting the greatest quantity without wearing the tool, but that wood will work best with a much greater velocity. The sheave contains both the metal coak and the wood sheave; and to give it the proper velocity for both, is the object of the contrivance in question. It is effected, by having two pulleys, or wheels, which give motion to the endless strap *X*. These are of equal size, and placed close together, their axis being in a line. One revolves with the velocity proper for turning brass, and the other for wood. Now in the commencement of the operation, when the tool works upon the coak only, the strap works upon the slowest of these two pulleys; but as the tool advances, and has got over the metal, and begins to cut the wood, the strap is shifted to the quick pulley, and turns the lathe with an increased velocity. The tool *a* is merely an angular point; but the slider *d* is so perfectly true and firm, that it cuts as even a surface as could be expected from a wider tool, and with this advantage, that the point will cut through every thing it meets with less danger of breaking than an edge. The tool is fitted into a holder, and held by the screw *b*, by loosening which it can be removed to make way for a sharp one. The lathe adapts itself readily for different sized sheaves. The chuck may be unscrewed from the end of the mandrel, and another put on. The screw *Y* will allow of any thickness; the nut *n*, on the end of the rod *g*, can be screwed along the rod, to adjust the diameter of the sheave; and the rest *N* can be drawn out in the same manner as any common lathe.

The machines for making the pins. As we are not able to present our readers with drawings of these machines, we have but little more to say of them than was mentioned in our list of the machines. The iron pins are forged between swages, by two men, in the usual way, being cylinders, except a small length at the end, which is left square for the purpose of holding in one of the cheeks of the block, to prevent the pin from turning round. These pins being centered by a simple tool, are carried to a lathe of immense strength. It has a short mandrel, and a back centre to support the extreme end of the pin. It has also a long slider fixed parallel to the pin, and provided with a rod similar to *g* in the last machine, which detaches the movement of the screw, when the whole length of the pin is turned. The holder of

VOL. III. PART II.

the tool has a small table fixed to it, which carries a vessel containing cold water, and provided with a cock, from which a continued stream of this water falls upon the tool. This is an essential provision, as the great strain of turning so large a piece of iron would certainly heat and soften the tool, which is of an excellent form for the purpose, being a cylindrical piece of steel cut obliquely, so as to form an elliptic section, the highest point of which forms the cutting edge. The tool is held in the same manner as the gouge of the shaping engine.

After being turned, the pins are burnished in a curious machine. It has a revolving spindle, placed vertically. The pin is fixed at the end of this, and, as it turns round, is forced down between three dies, or smooth pieces of hard steel, highly polished. These are fitted in a frame, and have screws behind them, by which they can be thrust forwards against the pin, to grasp it tight, and make such a pressure as will burnish down all the spiral scorings left by the turning lathe. The dies are immersed in oil to facilitate the operation, and prevent the dies from heating. The pins after this process are highly polished and fit for use.

Having now explained the mode of making all the parts of a block, its shell, sheave, and pin, it only remains to put them together, in which operation there is nothing singular or worthy of detail.

We shall conclude this article by observing, that these machines, with alterations, might be adapted to many useful purposes in the mechanical arts; particularly the mortising machine, which would be a most excellent tool for forming mortises in any pieces of work where a great number of similar pieces are required, so as to render it worth while to erect such an engine. Any person who has had the patience to stand by a carpenter while performing the tedious and laborious process of mortising through a large beam of wood, will judge of the importance of a machine which makes from 110 to 150 strokes per minute, and cuts at every stroke a chip as thick as pasteboard, with the most perfect accuracy. (J. F.)

We are proud in having had it in our power to present our readers with the first account of these valuable machines that has yet been given to the world; and we are fully compensated by this feeling, for the great labour and expence by which this object has been obtained. We hope, in the course of our work, to lay before our readers, other proofs of the great mechanical genius of Mr Brunell. (ED.)

BLOCKADE. See MILITARY TACTICS.

BLOIS, the BLESE, or CASTRUM BLESENSE of the Romans, a town of France, and capital of the department of the Loire and Cher, agreeably situated in a pleasant country, partly on a small eminence, and partly in a plain near the river Loire. Though the town itself is ill built, yet many of the public edifices are deserving of notice. The castle, which at first sight has the appearance of two separate buildings, that communicate by a passage through the rock, is the chief ornament of the town. A part of it was demolished in 1632 by the duke of Orleans, who built in its place a superb edifice, which is still unfinished. This castle was the birth-place of Louis XII. and the chambers in it are still shewn where the duke of Guise and his brother were assassinated, on the 23d December 1587, by order of Henry III. In the extensive

court before the castle is situated the Church of St Saviour, which is a handsome and large building. The cathedral, called the Church of St Solenne, the bridge of seven arches over the Loire, the Jesuits college, and the gates of the city, are the only other objects worthy of attention. The town is supplied with water by a large aqueduct, supposed to be built by the Romans, into which the water descends from the clefts of a rock, about three quarters of a mile from the city. The water is distributed from a large reservoir near the walls into fountains in different parts of the town. About six miles from Blois is the castle of Chambord, built by Francis I. and belonging to Marshal Saxe, who died there in 1751.

The commerce of Blois consists chiefly of brandy and wines, which are carried by the Loire to Orleans, Paris, Tours, Angers, Laval, and sometimes by land carriage to Normandy.

Blois carries on a considerable trade in serges, ticken, skins, gloves, hats, stockings, knives, &c. About 600 or 700 pieces of serges, &c. made of the wool of the country, are manufactured annually. The gloves of this place have been long held in great estimation. Population 13,312. E. Long. $1^{\circ} 20' 10''$, N. Lat. $47^{\circ} 35' 20''$. (π)

BLOOD. See ANATOMY and CHEMISTRY, but particularly PHYSIOLOGY.

BLOW-PIPE.

BLOW-PIPE, in chemistry, mineralogy, and the arts, is an extremely useful instrument, employed to raise an intense heat by the flame of a lamp or candle. It operates by throwing a rapid current of air through the flame, and by this means urging it violently against the object to be heated, which must necessarily be of small size. The blow-pipe is capable of throwing such a heat on a small object as would be difficult to obtain for a larger quantity of the same substance in the most powerful furnaces, and with this advantage, that the process is all the time under the inspection of the operator, whereas he can only conjecture what passes in the centre of a furnace. The stream of air for blow-pipes is usually raised by a blast from the mouth; in some instances by the vapour of boiling alcohol; and in others from bellows, or other pneumatic machines. We shall begin with blow-pipes of the first kind, as being the most simple and convenient. The common blow-pipe in use among artificers, consists of a conical metal tube, regularly tapering from the size convenient to be held in the mouth to the size of a small pin: The small end is bent with a regular curvature, so as to be nearly at right angles to the main tube. This pipe being held in the mouth, and a regular stream of air discharged through it into the flame of a candle, the flame is projected sidewise into a long conical spiracle of fire, which is of a blue colour at its root, or the part where it joins the flame; farther on it is of a yellow cast, growing more and more faint towards the extreme point. The object to be heated is held so that the flame strikes upon it; or, if it is large, it should be placed upon a piece of charcoal, which reverberates the flame forcibly on all sides of the object, and at the same time maintains the heat by its own combustion. This simple instrument is very effective in the hands of a dextrous operator; but the principal objection to it is, that, after using it a few minutes, the moisture of the air blown from the lungs is condensed, and accumulates in the tube till a drop is formed, which, by means of the current of air, is thrown so forcibly through the flame upon the object to be heated, as to cool it, and spoil the experiment. To remedy this defect, and render the instrument more convenient, many different forms have been proposed.

In consequence of an application to Mr Accum of Compton Street, London, that ingenious chemist has favoured us with a sight of all the blow-pipes which he keeps for sale, and we have gladly availed ourselves

of his permission to represent several of them in Plate LXII.

A very common blow-pipe, for chemical and mineralogical experiments, known by the name of Cronstad's Blow-pipe, is represented in Fig 1. It is the same as the common blow-pipe, above mentioned, except in having a globular ball at A. This unscrews in its largest diameter, to remove the moisture which may collect in it. The small pipe *a*, passing away from the ball, enters into it, and projects nearly into the centre, as is shown by the dotted lines, by which means the globe will hold more water than can ever be collected in it in the course of one experiment, without any danger of getting away at *a*. The mouthpiece B is made of ivory, and the rest of the pipe of brass; the nose *b*, or aperture through which the air issues, may be removed to screw on others of different sized holes. The pipe has generally three of these sizes; the smallest but just large enough to admit a bristle, and the largest only the size of a small pin.

The blow-pipe represented in Fig. 2. is attributed to Dr Black. It is simply a conical tin tube, of a convenient size to be held in the mouth at *a*, and enlarged to an inch diameter at the other end. The jet *b*, fixed to it at one side, is a short pipe soldered into the tube, and projecting inwards almost to its centre on the outer end. It is made conical, and a small jet *b* is stuck upon it. If well fitted, the friction will be quite sufficient to fasten it; and any number of jets may be adapted to fit on. This is a very good kind of blow-pipe, as the large internal surface of the conical tube effectually condenses the vapour of the breath, and affords a lodgment for it in the bottom of the tube. When it collects into a quantity so as to be troublesome, it may be poured out at the end *a*.

Fig. 5. is a convenient blow-pipe. Its ivory mouth-piece *a*, is fitted to the end of a brass tube A; and at the other end of this is soldered a small cylindrical box B, from the centre of which the jet *b* proceeds. This is fitted in by a joint, which allows the jet to be placed at any angle with the tube, a property which will frequently be found convenient in placing the flame in any direction. The joint is formed by a part of the jet, at right angles to the nose *b*, being fitted through a hole in the box; and the end, which comes through, rivetted down, at least so far as to prevent it coming out. The

box B has a lid *c*, which unscrews for the purpose of wiping out the dampness.

Fig. 4. is Dr Wollaston's ingenious portable blow-pipe, which is remarkable for its neatness, and the small space into which it may be packed. A is the mouth-piece, *b* a second length of the tube, receiving the conical end of the first, and *d* the jet, with a small globe *e*, which has a hole through it to admit the end of *b*. In the side of this is a hole, which, when the two are put together, coincides with the tube of the jet *d*. This pipe, when joined, has only the properties of the common blow-pipe before mentioned. When its parts are separated, as in the figure, the jet *e* is thrust into the large end of *b*, but the globe is left projecting out of the end; then both these are pushed into the tube A, at its large end, by which means, when put up, it is only the size of A, which is not larger than a small pencil, and may be always carried in the mineralogist's pocket-book; and in many instances will prove extremely useful when a better pipe is not at hand.

Fig. 5. is a blow-pipe, which has been handed to us by its inventor. It consists of two tubes A, B, of a tolerable size, soldered together like a hammer. The jets are screwed in at *a*, and the end of them projects some distance into the tube B, in order to prevent the water from being blown out. The jet *b*, at the opposite end, is for the escape of a part of the air. When blowing with a small jet, the quantity of air required is so small, that the operator would find relief in opening another, as he would then be enabled to breathe more frequently, and with greater ease.

It will readily be seen, that all the blow-pipes above described have advantages peculiar to themselves, though the differences between them are but trifling; and any of them will perform well, if supplied with a constant and equable stream of air, in which lies the principal art of using the blow-pipe. This is effected by the operator breathing freely through his nostrils, in the most natural manner, without breathing materially quicker or slower than ordinary; but at every expiration, throwing a portion of air into the mouth, so as to inflate the cheeks, which, by their muscular action, condense the air, and force it through the tube into the flame, in a continued stream, though the mouth is only supplied at the interval of every respiration. To perform this readily, requires some practice; and the facility of it can only be obtained by habit, it being one of those things which is not easily taught by words. If a person finds any difficulty in the first attempt, he will derive some advantage, from accustoming himself to breathe through the nostrils, first with the mouth open, and then shut; for in either of these cases, the passage from the lungs through the mouth is closed. Having acquired this habit, he should begin to throw some of the air, at each expiration into the mouth, as above described; suffering it to escape regularly through to the pipe, or any other tube held in the lips; but it should have a larger aperture than the jet of the blow-pipe, to render the operation more easy; and he must endeavour to compress the air by the cheeks, with an equable force; for the regularity of the blast materially depends on the regular pressure of the air. Every time, therefore, that the air is injected into the mouth, the cheeks will be swelled out by suffering the muscles to

relax in some degree, to enlarge the capacity of the mouth, and will gradually subside as the air issues forth, till a fresh supply inflates them. By this means the mouth will exactly imitate the action of the upper portion of a pair of smiths' bellows, and will regulate the blast on the same principle. The most effective application of the blast to the flame, is the next object of consideration. A lamp is sometimes used, but a candle is probably better. In either case, the flame which it raises must be considerable. The end pipe must be just entered into the flame, and the current of air will throw out a horizontal cone of flame from the opposite side. If it is well managed, the cone will be as distinct and well defined as possible, and extending often to the length of three inches. Care must be taken that the stream of air does not strike against any part of the wick, as it would then be divided, and the cone split into several. It is for this reason that a large flame is required, because the pipe must be somewhat above the wick; and unless the flame is considerable, there will not be sufficient at that part for the stream of air to act upon. In order to increase the flame, it is proper to allow the candle to burn till it has a considerable length of snuff; and this should be opened out into numerous heads, or the wick turned down, so as to expose the largest surface, and cause the greatest flame. The pipe should then be directed through that part of the flame where the combustion appears to be the most perfect and brilliant. By examining the horizontal cone of flame, it appears to be formed of two, the interior cone being blue, and the external yellow, which is therefore the longest, and terminates the flame: the blue being so much deeper in colour, gives the base of the cone the appearance of being blue and capped with yellow. The subject of experiment is held in the yellow flame till it becomes red hot, and is then advanced towards the candle, to bring it into the blue flame, where it receives the greatest heat. It is held in the small platina spoon, Fig. 6, which has the advantage of reflecting the flame from all sides upon the object; and though this does not perhaps actually increase the heat thrown upon the object, it creates an atmosphere of flame and heated air around it, which prevents the object being so much cooled, if it should for an instant be moved out of the cone flame, from the unsteadiness of the hand in holding the pipe or the spoon, or from accidental currents of air which would disturb the flame, and cause such a wavering in the point of the cone, as to divert it, in some measure, from the object.

The most expert operators with the blow-pipe find, that after they have attained the art of blowing with the most perfect regularity, they sometimes fail in the course of a long experiment, by a tremulous motion which seizes the lips, from the fatigue of holding the pipe so long, with a sufficient force, to prevent the escape of the air by the sides of it. This causes such a motion of the pipe, that the flame is too unsteady to produce a proper effect upon the object. When charcoal is used to support the subject of experiment, it should be of a close compact grain, and properly burnt; for if it is too little carbonised, it will flame like a piece of wood, and obscure the object; and if it is too much burnt, it is so quickly consumed and burned to ashes, that the object is in danger of being lost in it. The

charcoal greatly increases the heat; but we are disposed to think that this arises more from the cause to which we have ascribed it in the case of the platina spoon, than from its own combustion, though this has doubtless some effect in heating the object at the opposite side.

The great heat raised from the blow-pipe has been a matter of surprise to many philosophers; for it does not appear to act by increasing the combustion, as is the case in bellows applied to a furnace; it must therefore act by projecting the heat mechanically upon the object, with a greater force and velocity than when it receives it by the mere application of the flame. This opinion is founded upon some experiments made by Count Rumford, which will be found in vol. ii. of his *Essays*. The difficulty of managing the mouth blow-pipe, has induced many operators, to employ the glass-blowers lamp. This is a table, with a pair of double bellows, fixed beneath it, and worked by the foot. Upon the table, a lamp, or rather a dish of melted tallow, is placed, with a large cotton wick hanging over the side of it. The flame of this is blown by a nose-pipe fixed above the table, and having universal motion. This machine is extremely useful in many of the arts, for softening and bending glass tubes, and for forming any small vessels in glass; and, indeed, it is by this means that all small glasses are blown, as we shall describe under *GLASS Blowing*. This instrument is not at all convenient for the purpose of experiments, as the motion of the body caused by blowing with the foot, prevents the object from being held with the requisite steadiness; though it is extremely useful to the artist for soldering small things in metal, hardening small drills, enamelling, and many other purposes.

In order to have an apparatus at once convenient, steady, and powerful, the alcohol blow-pipes have been invented. Two of these are represented in Plate LXII.

The first, Fig. 7. is the invention of Professor Pictet of Geneva, and consists of an oval vessel AB, filled with oil, and having two wicks at C and D. The former is for the flame, which is to be blown, and the other is smaller, being intended to heat a small boiler E, which is filled with spirits of wine. On the top of this boiler, a syphon tube F is screwed, which turns down, and presents its jet *e* to the flame of the wick C. The boiler is fitted into a ring, which is supported by a collar sliding up and down on a wire G, and can be fastened by a screw S at any elevation. The nose can be moved side-wise on its wire to meet the flame; and its distance from the flame may be varied, by turning the socket of the wick round. The wick not being in the centre of the socket, of course traverses in a small circle. The jet unscrews at *e*, to change it for a larger or smaller aperture. This blow-pipe operates by the alcohol being boiled by the heat of the lamp D, and its steam or vapour passing over through the syphon tube to the flame at C. Its advantages are, steadiness of the flame, and, at the same time, the inflammable vapour very greatly increases the effect. The only objection to it is, the expense of alcohol and the two lamps.

Fig. 8. is another form of the same instrument, proposed by Mr Benj. Hook. Here the boiler is a globe B, supported in a ring fixed on two pillars *aa*. Between these, a small lamp E slides up and down, and is retained at any height, by the friction of two small springs.

This lamp at the same time heats the boiler B, and its flame is urged by the vapour which issues at a pipe I. This passes through the boiler, and rises up above the surface of the spirit, so that there is no danger of its boiling over into the tube. At G is a valve, loaded with a weight acting as a safety valve, to permit the escape of the vapour, if it should become so strong as to endanger the rupture of the vessel; and at H is a screw plug, through which the alcohol is introduced. This instrument acts in the same manner as that before described; and the adjustment of the distance of the wick from the jet is affected in the same manner. The alcohol blow-pipes are not a new invention, one being described by the abbé Nollet, in his *Art des Experiences*, published in 1770. They have, however, but lately been brought into use, and are found to answer extremely well for small experiments, where the consumption of alcohol is not serious.

From what we have already said, our readers will form some idea of the requisites for a good blow-pipe; and we beg to present them with one, constructed on the same plan as the great blowing engines for the iron furnaces. It is represented in Fig. 9. of Plate LXII. where AB is a vessel of japanned tin or glass, containing water, and C another included within the former, and closed by a dome at top, and open at the bottom. It is supported in the other vessel by a ring or cover, soldered to both, and perforated with several holes, as shewn in the Figure. On the top of the dome, a short brass tube is soldered, the outside of which is made conical, for the reception of a socket, projecting from the side of a common blow-pipe D. The mouth-piece of this blow-pipe is made globular at *a*, and a short tube *b* is fitted into it, with a valve adapted to the end of it, shutting outwards, so as to prevent the return of any air into the mouth. At the other end of the blow-pipe, a curved tube *d* is fitted on, which has the jet at the end of it. The lamp E is situated on the top of a pedestal, and can be raised or lowered at pleasure, by means of the rivetted nut F. This nut fits upon a screw formed on the stem of the lamp, the lower part of which stem is made square, to prevent it turning round by the action of the nut. The vessel makes a steady support for blow-pipes, which is used by applying the mouth to the tube *b*, and throwing air into the interior vessel C; this expels the water at the lower end of it into the external vessel; and the pressure of the water to return to its original level, causes a constant compression of the air, and forces it through the jet into the flame of the lamp. By this means it is not necessary to blow constantly with the mouth; for if the air is forced into the receiver at intervals, the pressure of the water will expel it in a constant stream, and the operator will not be fatigued by any of the causes above enumerated; or he may take his mouth from the pipe at any time for a few seconds, without interrupting the stream; and he may take the air into his mouth, and blow it into the tube, so as to supply it with pure atmospheric air, instead of that which has passed into the lungs: or if it is more convenient, he may employ an assistant to blow. The socket which connects the blow-pipe with the dome C, is made conical, and fits on very stiff, so as to fix the blow-pipe very firm, at the same time that it admits the pipe to have an angular motion. To adjust its distance from the frame, the joint connecting the jet *d* with the pipe, is

fitted in the same manner, to admit of changing the elevation of the jet; and a jet of any other form or size may be fitted on at the same joint. It will easily be seen, that this blow-pipe may be adapted to blow with oxygen gas, by connecting a flexible tube with the mouth-piece *b*. The gas is injected into this pipe from a bladder filled with gas, by means well known to chemists.

The heat raised by oxygen gas, when projected through a blow-pipe upon a piece of burning charcoal, excites the greatest heat that is known.* Some very interesting experiments upon this subject were made at the London Philosophical Society in 1798, and are detailed in the *Philosophical Magazine*, vol. viii. The nose pipes, which were used in these experiments, are shewn in Fig. 10. The socket A receives a pipe coming from the gasometer, which contains the gas. Upon this pipe are two brass boxes *d* and *e*, into which are fitted the tubes *f*, *g*, which turn in these boxes, air tight, for the purpose of enabling the operator to move the blow-pipes *h*, *i* nearer or farther from each other. The blow-pipes *h*, *i* also turn at *k*, *l*, in the tubes *f*, *g*, to enable the operator to alter the direction of the streams, and make them fall on the charcoal *m*, at any angle he pleases. This apparatus may be adapted to fit on the end of the blow-pipe, Fig. 9. and may, with very little alteration, be constructed to throw the flame of two lamps into one focus, as has been proposed by a gentleman in America.†

† BLOW-PIPE, COMPOUND. This appellation has been given to a modification of the blow-pipe, by which the greatest heat known has been produced. It is an invention of Robert Hare, of Philadelphia, M. A. P. S. A description of it, a theoretical explanation, and a detail of its effects, were published in a memoir in 1802, republished in the 14th vol. Phil. Mag. London, and in the *Annales de Chimie*, Tom. 45, Paris. A paper containing an account of some additional experiments was subsequently communicated in the first part, 6th vol. of the *American Phil. Trans.* The construction of the compound blow-pipe, and the considerations which led to the contrivance of it, are thus explained by the inventor.

“In operating with the combustion of carbon and oxygen gas, great evils were observed to result from the difficulty of placing the subject of the operation in the focus of the heat, without interrupting the stream of air by which this heat was supported. Not only was the focus widened by this interruption, and the intensity of the heat thereby lessened; but the stream of air oxidated those substances which were combustible, and cooled those which were otherwise, in the places where it impinged previously to its union with the charcoal. Added to this, the charcoal was so rapidly consumed, that the substance acted on became so much buried, that it was difficult to follow it with the eye, or the orifice of the pipe; and some substances were observed to run into the pores of the coal, and elude examination.

To avoid these evils, it was thought desirable that means might be discovered of clothing the upper surface of any body which might be subjected to this species of operation with some burning matter, of which the heat might be equal to that produced by the carbon,

An inconvenience sometimes occurs in using the inverted receiver: When the blowing stops, and the pressure

with which the lower surface might be in contact; or by which bodies might be exposed on solid supports to a temperature equal or superior to that of the porous charcoal uniting with oxygen.

It soon occurred, that these objects might be attained by means of flame supported by the hydrogen and oxygen gases; for it was conceived that, according to the admirable theory of the French chemists, more caloric ought to be extricated by this than by any other combustion.

By the union of the bases of the hydrogen and oxygen gases, not only is all the caloric of the oxygen gas evolved, but also a much larger quantity, which must be necessary to give the particles of the hydrogen their superior power of repulsion. The product is water in the state of steam, which retains heat so slightly, that it acts merely as a vehicle to deliver it to other bodies. What is necessary to preserve to water its form of fluidity is the only portion of caloric permanently neutralized.

The combustion of carbon with oxygen gas has been hitherto considered as the hottest of all fires. The caloric evolved in this case proceeds from the oxygen gas alone, while the product is carbonic acid gas, which abstracts the large quantity of caloric, necessary to give it the form of permanent air, but which adds nothing to the intensity of the heat. Hence it is evident, that more caloric is evolved, and less abstracted, in combustion supported by the hydrogen and oxygen gases, than in that supported by oxygen gas and carbon.

However, the intensity of the heat of combustion is not only dependent on the quantity of caloric extricated, but also on the comparative smallness of the time and space in which the extrication is accomplished. But in this respect the æriiform combustible has obviously the advantage over those which are solid, as its fluid and elastic properties render it susceptible of being rapidly precipitated into a focus, and of the most speedy mixture with the oxidating principle when arrived there.

The opinion of the intensity of the heat produced by the hydrogen and oxygen gases thus upheld by theory, derives additional support from the practical observation of the great heat of a flame supported by hydrogen gas while issuing from a pipe; and also of the violent explosion which takes place when it is mixed with oxygen gas and ignited; for it appears that this explosion can only be attributed to the combination of an immense quantity of caloric with the water which is either held in solution by these gases, or formed by the union of their bases.

Such was the reasoning which gave rise to the desire of employing the flame of the hydrogen and oxygen gases. But before this could be accomplished, it was necessary to overcome the difficulty of igniting a mixture of these æriiform substances without the danger of an explosion. For the purpose of surmounting this difficulty, two common brass blow-pipes, Fig. 11, were joined at their orifices to two perforations in a conical frus-

* See the subjoined account of the experiments of R. Hare and professor Silliman.

of the water forces the air from the internal receiver, the momentum of the water rising upon it, is such as

to dash up into the pipe, and put out the lamp. To prevent this, a wire is soldered to the bottom of the out-

tum of pure silver, of which the mean diameter is one-third, and the length is three-fourths of an inch. The diameter of one of these holes is large enough for the admission of a common brass pin. The other hole is a third less. They commence separately on the upper surface of the silver frustum near the circumference, and converge so as to meet in a point at the distance of a line and a half from the lower surface. In the space between the lower surface and the point of meeting, there is a perforation of the same diameter as the larger hole. The manner in which this perforation and the tubular holes communicate one with the other, may be understood from the lines in the form of the letter Y, in the representation of the silver conical frustum at d."

Having connected one of the branches of the instrument thus constructed, with a reservoir containing oxygen gas, and the other with a reservoir containing hydrogen gas by means of pipes furnished with stop cocks, the author proceeds:

"The cock of the pipe communicating with the hydrogen gas was turned until as much was emitted from the orifice of the cylinder as when lighted formed a flame smaller in size than that of a candle. Under this flame was placed the body to be acted on, supported either by charcoal, or by some more solid and incombustible substance. The cock retaining the oxygen gas was then turned, until the heat and light appeared to have attained the greatest intensity. When this took place, the eyes could scarcely sustain the one, nor could the most refractory substances resist the other."

For supplying the common or compound blow-pipe with air or gas, R. Hare employed a peculiar apparatus. But it must be evident that if the gases be made to flow from the orifice of the compound blow-pipe with the requisite velocity, it must be immaterial how they may be supplied. We give an engraving, Fig. 12, of a simple apparatus for this purpose, subsequently employed by the inventor. It is constructed on a principle similar to one contrived by R. Hare, in conjunction with professor Silliman, and which has been employed by the latter during his lectures, as a gas holder and pneumatic tub. A, Cistern to be kept nearly full of water; B C, two reservoirs for containing the gases; D E, pipes for conveying them to the compound blow-pipe, F G H. This is an improved construction by professor Silliman. The pipes F G are of pure silver, and screwed into the piece H, which is of platinum. This part of the apparatus is attached to the large curved tubes D E, by double screws which are seen above. The cocks at B C are for assaying the purity of the gases in the reservoirs. The latter may be filled by a pipe passing under them from the retort in which the gas may be extricated, or by the vessel represented at Fig. 13. This may be filled, as is usual, in the pneumatic apparatus, and being depressed by means of the handle A, in the space between the reservoir, till the nozzle of the cock may be placed under them and the key of it turned by the handle B; the gas which it may contain, will be expelled from it into them. The water will consequently be displaced from the interior of the reservoirs, and rise higher above them

externally. To remove the excess of it, the vessel represented at Fig. 14, may be employed. Opening the cock on the top it is only necessary to depress it into the space between the reservoirs. The water will rise into it through the hole which may be observed in the side near the bottom; the cock being then closed and this hole kept under the surface of the fluid, the vessel may, without any loss of its contents, be lifted on the top of the reservoir, which serves as a shelf of a hydro-pneumatic tub. But when the expenditure of gas from the reservoirs causes the surface of the water in the cistern to decline below the hole, that contained in the vessel will run out and tend to remedy the deficiency. By plugging the hole in the side of the vessel, the latter may be removed from the cistern.

Two or more of these vessels may be found useful. Indeed when the gases are left any length of time in the reservoirs, it will be expedient to reduce the height of the water in the cistern, as the pressure arising from it, promotes absorption and leakage.

The table K, and its stand supported by a screw I, are employed to adjust the situation of bodies exposed to the flame.

It will be evident from inspection, that the cistern is applicable to the purposes of the pneumatic tub, and that by a tube curved round the table, a blow-pipe may be made to excite a flame, with either oxygen gas or atmospheric air. To furnish a flame for this purpose, a lamp may be placed on the moveable stand at I.

The following account of the invention, and some experiments recently tried, was communicated by Professor Silliman, to the Connecticut Academy of Arts and Sciences.

Experiments on the fusion of various refractory bodies by the Compound Blow-Pipe of R. Hare.

The philosophical world beheld with pleasure and astonishment, the effects produced on the fusion and combustion of bodies, by a stream of oxygen gas, directed upon burning charcoal. The splendour of these experiments arrested universal attention, and Lavoisier with his gazo-meter was enabled, in this manner to produce a degree of heat surpassing that of the most powerful furnaces, and even of the solar focus. Bodies which no degree of heat, previous applied had been able to soften, now became fluid and philosophy appeared to have attained the limit of its power in exciting heat; indeed, it seemed to have advanced very far towards realizing the opinion, that solidity and fluidity are accidental attributes of bodies, dependent solely on the quantity of caloric which they contain, and that therefore, they may be supposed capable of existing in either of these conditions.

Still, however, there were, *in fact*, many important exceptions. Of the primitive earths, Lavoisier had been enabled to fuse only alumine, while the rest remained refractory, and seemed fully entitled to the character of infusibility usually attributed to this class of bodies. Many native minerals and especially those which are most distinguished for hardness, beauty, and simplicity of composition, maintained the same character, and

side cistern, and extends upward through its whole height. Upon this wire a cork slides, and always floats

upon the surface of the water; so that it rises above its proper level, this cork rises, and forms a plug to

some of them refused to melt even when heated with powerful fluxes.

The beautiful invention of Robert Hare of Philadelphia, by which he succeeded in burning, with safety and convenience, the united stream of oxygen and hydrogen gases, greatly extended our dominion over refractory bodies, and presented new and very interesting results. R. Hare's memoir, originally communicated to the Chemical Society of Philadelphia, has been some years before the public, and has been republished and handsomely noticed, both in France and England. Still, however, his results have not found their way into the systematical books on chemistry, (with the exception of Mr Murray's system,) notwithstanding that some of the European professors have availed themselves of R. Hare's invention, so far as to exhibit his most splendid and striking experiments to their classes.

It will be necessary to recollect, that R. Hare not only melted alumine, which Lavoisier had done before, but also *silex* and *barytes*, and, by subsequent experiments, he added *strontites* to the list of fusible bodies: he was inclined to believe that he had volatilized gold and silver, a conclusion which was rendered highly probable by his having afterwards evidently volatilized platinum.

The experiments of R. Hare, as will appear below, have been repeated by the writer of this paper with success, and many other bodies among the most refractory in nature, have been melted. For the sake of shewing how far the experiments now to be recited have affected our knowledge of the dominion of heat, quotations, for comparison, will occasionally be made, from one of the latest and most respectable chemical authorities. (Murray's *System*, 2d edit.)

Bodies submitted to the heat of the Compound Blow-Pipe of R. Hare.

PRIMITIVE EARTHS.

Silex, being in a fine powder, was blown away by the current of gas; but when moistened with water, it became agglutinated by the heat, and was then perfectly fused into a colourless glass.

Alumine, perfectly fused, into a milk white enamel.

Barytes, fused immediately with intumescence, owing to water, as observed by Lavoisier, it then became solid and dry, but soon melted again into a perfect globe, forming a greyish white enamel.

Strontites, the same.

Glucine, perfectly fused into a white enamel.

Zircon, the same.

Lime, in small pieces, it was immediately blown off from the charcoal. To prevent this, as well as to obviate the suspicion that any foreign matter had contributed to its fusion, the following expedient was resorted to:—A piece of lime, from the Carrara marble, was strongly ignited, in a covered platinum crucible. One angle of it was then shaped into a small cylinder, about one fourth of an inch high, and somewhat thicker than a great pin. The cylinder remained in connection with the piece of lime: this was held by a pair of forceps, and thus the

small cylinder of lime was brought into contact with the heat, without danger of being blown away, and without a possibility of contamination. There was this farther advantage, (as the experiment was delicate, and the determination of the result might be difficult,) that, as the cylinder was held in a perpendicular position, if the lime did really melt, the column must sink and become, at least to a degree, blended with the supporting mass of lime. When the compound flame fell upon the lime, the splendour of the light was perfectly insupportable, by the naked eye, and when viewed through deep coloured glasses, (as indeed all these experiments ought to be,) the lime was seen to become rounded at the angles, and gradually to sink, till, in the course of a few seconds, only a small globular protuberance remained, and the mass of supporting lime was also superficially fused at the base of the column, through a space of half an inch in diameter.

The protuberance, as well as the contiguous portion of lime, was converted into a perfectly white and glistening enamel. A magnifying glass discovered a few minute pores, but not the slightest earthy appearance. This experiment was repeated several times, and with uniform success. May not lime therefore be added to the list of fusible bodies?

Magnesia. The same circumstances that rendered the operating upon lime difficult, existed, in a still greater degree, with respect to magnesia. Its lightness and pulverulent form rendered it impossible to confine it for a moment upon the charcoal, and as it has very little cohesion, it could not be shaped by the knife as the lime had been. After being calcined, at full ignition, in a covered platinum crucible, it was kneaded with water, till it became of the consistence of dough. It was then shaped into a rude cone as acute as might be, but still very blunt. The cone was three-fourths of an inch long, and was supported upon a coiled wire.

The magnesia, thus prepared, was exposed to the compound flame. The escape of the water caused the vertex of the cone to fly off in repeated flakes, and the top of the frustum that thus remained gave nearly as powerful a reflection of light as the lime had done. From the bulk of the piece, (it being now one-fourth of an inch diameter at the part where the flame was applied,) no perceptible sinking could be expected. After a few seconds, the piece being examined with a magnifying glass, no roughnesses or earthy particles could be perceived on the top, but a number of glossy, smooth protuberances, whose surface was a perfectly white enamel. This experiment was repeated with the same success. May not magnesia, then, be also added to the table of fusible bodies?

Yttria was the only remaining primitive earth, but no specimen of it could be obtained. Perhaps, then, we shall be justified in saying in future that the primitive earths are fusible bodies, although not fusible in furnaces, in the solar focus, nor (with the exception of alumine, and, possibly, barytes,) even by a stream of oxygen gas directed upon burning charcoal.

Platinum was not only melted, but volatilized with strong ebullition.

close the orifice in the top of the dome, and prevent the water from getting out. For farther information on

blow-pipes, see Leblond, in Rozier's *Journal*, tom. xxx p. 92. Haas, in Nicholson's *Journal*, 8vo. vol. iii. p. 119.

VARIOUS MINERALS.

Rock Crystal, transparent and colourless. This mineral was instantly melted into a beautiful white glass.

"It not only does not melt in the focus of the most powerful burning mirror, but, it remains without fusion, at least when in the state of rock crystal, in the still more intense heat, excited by a stream of oxygen gas directed on burning charcoal." (Murray, ii. 261.)

"It is even imperfectly softened by the intense heat, excited by a stream of oxygen gas, directed on the flame of the blow-pipe lamp." (*Ibid.* iii. 513.)

Common Quartz, fused immediately into a vitreous globule.

Gun Flint melted with equal rapidity. It first became white, and the fusion was attended with ebullition and a separation of numerous small ignited globules which seemed to burn away as they rolled out of the current of flame. The production of this fusion was a beautiful splendid enamel. "It is infusible before the blow-pipe, but loses its colour." (*Ibid.* 518.)

Chalcedony, melted rapidly, and gave a beautiful bluish white enamel resembling opal. "It is infusible before the blow-pipe." (*Ibid.* 516.)

Oriental Carnelian, fused with ebullition, and produced a semi-transparent white globule with a fine lustre.

Red Jasper, from the Grampians, was slowly fused with a sluggish effervescence. It gave a greyish black slag, with white spots.

"It is infusible before the blow-pipe, even when the flame is excited by a stream of oxygen gas." (*Ibid.* 519.)

Smoky Quartz, or smoky topaz, melted into a colourless globule.

Beryl, melted instantly into a perfect globule, and continued in violent ebullition, as long as the flame was applied, and when, after the globule became cold, it was heated again, the ebullition was equally renewed. The globule was a glass of a beautiful bluish milky white.

"The beryl is melted with difficulty before the blow-pipe alone, but easily when borax is added." (*Ibid.* 511.)

Emerald of Peru, the same, only the globule was green, and perfectly transparent.

Olivin, fused into a dark brown globule, almost black. "It can scarcely be melted by the blow-pipe without addition." (*Ibid.* 534.)

Pesuvian instantly melted into a beautiful green glass. "It melts before the blow-pipe into a yellowish glass." (*Ibid.* 534.)

Leucite instantly fused into a perfectly transparent white glass; the fusion was attended with strong ebullition, and many ignited globules darted from it and burnt in the air, or rolled out upon the charcoal, and then burned. Were they not potassium? This stone contains full 20 per cent. of potash; this hint will be resumed below. "It is not fused before the blow-pipe." (Murray, iii. 554.)

Chrysoberyl, (Cynophane of Haüy) was immediately fused into a greyish white globule. "It is not melted by the blow-pipe." (*Ibid.* 499.)

Topaz of Saxony, melted with strong ebullition, and became a white enamel. "It is infusible upon the blow-pipe, but melts when borax is added." (*Ibid.* 498.)

Saffar or Ryanite perfectly and instantly fused, with ebullition, into a white enamel. "It remains perfectly unaltered before the flame of the blow-pipe, even when excited by oxygen gas." (*Ibid.* 499.)

Corundum, of the East Indies, was immediately and perfectly fused into a grey globule.

Corundum, of China, the same with active ebullition, "is not fused by the flame of the blow-pipe on charcoal, even when soda or borax is added to it." (*Ibid.* 495.)

Zircon, of Ceylon, melted with ebullition, into a white enamel. "It is not melted alone before the flame of the blow-pipe, but if borax is added it forms a transparent glass." (Murray, iii. 539.)

Hyacinth, of Expailly, fused into a white enamel, "It loses its colour before the flame of the blow-pipe, but it is not fused; it melts with borax into a transparent glass." (*Ibid.* 540.)

Cinnamon Stone instantly fused into a black globule with violent ebullition.

Spinelle Ruby fused immediately into an elliptical red globule. "It does not melt before the blow-pipe, but is fused by the aid of borax." (*Ibid.* 497.)

Steatite melted with strong ebullition into a greyish slag. "It does not melt before the blow-pipe, but becomes white and very hard." (*Ibid.* 482.)

Porcelain, common pottery, fragments of Hessian crucibles, Wedgwood's ware, various natural clays, as pipe and porcelain clay, fine and common brick, and compound rocks, &c. were fused with equal ease.

During the action of the compound flame upon the alkaline earths, provided they were supported by charcoal, distinct globules often rolled and darted out from the ignited mass, and burnt, sometimes vividly, and with peculiarly coloured flame. From the nature of the experiments, it will not be easy to prove, that these globules were the bases of the earths, and yet there is the strongest reason to believe it. Circumstances could scarcely be devised, more favourable to the simultaneous fusion and decomposition of these bodies, than when supported by charcoal highly ignited, and surrounded by hydrogen also in a state of intense ignition. That metallic oxides should be reduced when thus situated is not surprising; but the current of oxygen gas emitted from the pipe reoxidates the metalloids as soon as they escape from that part of the focus where the exuberancy of combustible matter favours their revival. If means could be devised to obviate this difficulty, the blow-pipe of R. Hare might become an important instrument of analytical research.

We can scarcely fail to attribute some of the appearances, during the fusion of the leucite, to the decomposition of the potash it contains.

This impression was much strengthened, by exposing potash and soda to the compound flame, with a support of charcoal; they were evidently decomposed; numerous distinct globules rolled out from them, and burnt with the peculiar vivid white light, and flash, which these metalloids exhibit, when produced and ignited in the galvanic circuit. It is hoped that these hints may induce a farther investigation of this subject.

BLOWING, an operation by which a continued stream of air is projected with great force and velocity into a furnace, for the purpose of increasing its combustion.

When large bellows are employed for this purpose, or when the air is pumped from a cylinder directly into the furnace, it is introduced in irregular puffs, which are completely insufficient for the intended purpose. In order to equalise and continue the blast, three different contrivances have been adopted. The first method is by a regulating cylinder, which is fitted with a piston heavily loaded, having at least three pounds on the square inch. The air which is pumped from the blowing cylinder, passes into the regulating cylinder, and as this cannot escape, it will, of course, raise the loaded piston. The twere, or pipe, which conveys the air out of this cylinder into the furnace, is connected with this cylinder, so that when the mouth of the twere is open, the air will rush from the regulating cylinder into the furnace, and the weight of the loaded piston will force the air through the twere with a constant blast, during the intervals between each stroke of the piston of the blowing cylinder. This method was originally adopted in blast furnaces; but though the quality of the air is subject to little alteration from any change in the atmosphere, yet the regulating cylinder has several disadvantages. Owing to the small capacity of this cylinder, the blast is not altogether free from irregularities. A considerable quantity of dense air, likewise, escapes by the sides of the piston; and if this is remedied by fitting the piston closer to the cylinder, the friction is so much increased, that the piston does not follow the air fast enough down, and the blast weakens a little at the end of every stroke; while at the beginning of the succeeding stroke, the air must overcome this friction before the piston will rise, and hence another puff accompanies the commencement of each stroke.

The second method of equalizing the blast, is by discharging the air from the blowing cylinder into an airtight apartment, or air vault, the air being prevented from returning into the cylinder by a valve. Let us suppose that the air vault is of such a size as to contain 100 fulls of the blowing cylinder, and that the nose pipe, which discharges the air into the furnace, is stopped. After the engine has made 25 strokes, and forced into the air vault 25 cylinders of air, the air vault will then contain 125 cylinders of air in a state of condensation, and having a force of three pounds upon the square inch. Let the nose pipe be now opened, and let it be of such a size as to discharge one full of the blowing cylinder during one stroke of the engine. The blowing cylinder will then supply the air vault as fast as the air is carried off by the twere, and the blast will be very equal; the end of each blast being only about two parts weaker than the beginning of the blast. It is obvious, that the elasticity of the condensed air will keep up the regularity of the blast during the intervals between each stroke of the engine. The air vault at the Devon iron works is excavated out of the solid rock. It is 72 feet long, 14 feet wide, and 13 feet high, and contains about

13,000 cubic feet of air. Mr Mushet is of opinion, that the air from the air vault is of a very bad quality for the purpose for which it is required. "This immense magazine of compressed air," he observes, "generates a considerable portion of heat, which greedily seizes the damp which are unavoidable in under ground excavations, and conveys them to the furnace. In the summer months, the air becomes so debased, as to affect the quality of the iron, and change it from grey to white. Every change in the temperature of the atmosphere, during this period, is indicated by various changes in the furnace."

The third method of equalizing the blast is, by the water vault, or water regulator, which is described in the following article, and represented in Plate LXIII. The water regulator has the advantage of a steady and cold blast. No air is lost, as in the case of the regulating cylinder, and no irregularity arises from friction. The air, however, always contains a considerable portion of moisture from its being in contact with water; and the blast is so cold, that the temperature of the discharged air seldom exceeds 38°, when the temperature of the atmosphere is 60°—65° and 70°.

The effect of the blowing engine depends, in a considerable degree, on the density of the air, and the velocity with which it enters the furnace. Mr Mushet is of opinion, that the area of the discharging pipe, and the compression of the blast, depend on the qualities of the coals employed. "A soft or mixed quality of coal," he observes, "is more susceptible of combustion than either the splint or clod coal; the consequences of which is, that unless the necessary compression of air is used, decomposition is too early accomplished, and the coals become oxygenated by combustion in a greater ratio than is proper for the carbonation of the metal. To avoid this, the column of air ought to be discharged, in the case of soft coals, under such a degree of compression as to resist entire decomposition in the ignited passage." From this cause, the density of the blast should vary from 2 to 3½ pounds in the square inch. Mr Roebuck supposes, that, "with the given power, it is rather by a great quantity of air thrown into the furnace with a moderate velocity, than by a less quantity thrown in with a greater velocity, that the greatest benefit is derived in the smelting of iron stones in order to produce pig iron." "Chemically speaking," says Dr Robison, "it seems to be the quantity, not the density of the air, which renders it effective in the iron furnace. Yet I can conceive a great quantity of air sent through a furnace without effect, because, being spread through much of the materials, it consumes the fuel too slowly in the different parts of the furnace for raising the smelting heat, whereas the same quantity made more dense, by crowding it into one part of the fuel, will rapidly consume it, and give out all its heat in a very narrow space, and thus produces effects which cannot be produced in any other way." For some of the preceding observations, we have been indebted to a manuscript paper of the late Professor John Robison, which, we believe, was the last production of that distinguished philosopher. It is an answer to several queries of Mr Grieve respecting blowing engines; and we hope to have it in our power to present it to our readers in a future part of our work. For farther information on the subject of this article, see Smeaton's *Reports*; Roebuck, *Phil. Trans. Edin.* vol. v. p. 31.; and Mushet, *Phil. Mag.* vol. vi. p. 60, 113, 362. (π)

BLOWING ENGINE.

BLOWING ENGINE, is a machine for forcing air with great velocity into a furnace in order to increase the combustion, and is now used in all the practical operations of metallurgy.

The machine first employed for this purpose was a pair of leather bellows wrought by the hand; but when it became necessary to smelt iron in large quantities, the size and number of the bellows were increased. Two pairs of bellows were so connected by means of a lever, that the one pair shut when the other opened. The handle of each pair was successively moved by two cogs, placed at right angles to each other on the horizontal axis of a water wheel; so that during the revolution of the wheel, one of the cogs shut one pair of bellows, and forced the included air into the furnace, while the other, which was at this instant opened, was shut by means of the other cog, and thus discharged its contents into the furnace. By this means a continued blast is kept up, excepting a trifling pause when the motion is changed. A machine similar to this, called the slag-mill, is used for refining the lava from the reverberating furnace in which lead ore is smelted.

Another engine, called the water blowing machine, has been used for producing a strong blast. It has been pretty generally adopted on the continent for more than a century, but does not seem to have come into use in this country. A current of water is made to pass through a kind of cullendar placed in the open air, and perforated with a number of triangular holes. The water descends through these apertures in many small streams, and by exposing a great surface to the atmosphere, it drags along with it an immense quantity of air, and is conveyed through a tube till it dashes against a stone pedestal inclosed in a large vessel. The mixture of air and water which falls upon the pedestal is dispersed in every direction; the air is separated from the water; it ascends to the upper part of the vessel, and rushes through a pipe to the furnace, while the water descends through apertures at the bottom of the vessel.

Fabri and Dietrich imagined, that the wind is occasioned by the decomposition of the water, or its transformation into gas in consequence of the agitation and percussion of its parts; but M. Venturi, (*Experimental Inquiry concerning the lateral communication of motion in Fluids*, Prop. VIII.) to whom we are indebted for the first philosophical account of this machine, has shewn, that this opinion is erroneous, and that the wind is supplied from the atmosphere; for when the lateral openings were shut, no wind was generated.

Hence the principal object in the construction of these machines is, to combine as much air as possible with the descending current. With this view, the water is often made to pass through a cullendar, as already mentioned.

Franciscus Tertius de Lanis, (*Magistero Nat. et Artis*, lib. v. cap. 3.) observes, that he has seen a greater wind generated by a machine of this kind, than could be produced by bellows ten or twelve feet long.*

Machines of such a nature might have been sufficient for smelting iron when charcoal was used for fuel, as in other countries; but when coal began to be used, it became necessary to construct machines capable of affording a powerful and constant blast, and formed of the most durable materials.

The earliest contrivance of this kind was a forcing

pump, worked by a water wheel, or a steam engine; and it would appear, that the first cylinders of this kind, at least those of any magnitude, were erected by Mr John Smeaton, in 1760, at the Carron iron works. The pumps were wrought alternately by a water wheel, having four cranks upon its axis, each of which moved the piston of a cylinder, which had a stroke of four feet six inches; the diameter of each cylinder being also four feet six inches.

In situations where a fall of water could not be obtained, steam engines were employed to work the pumps; but as these machines were then only single, the piston descending by the pressure of the atmosphere, it was necessary to have some contrivance for producing a continued stream of air during the descent of the piston. This object was effected, by receiving the air into a regulating cylinder of the same size as the blowing cylinder, and furnished with a piston loaded with heavy weights. As every stroke of the engine would pump into this cylinder twice the quantity of air that would pass through the nose pipe into the furnace in the same time, the air raised the loaded piston of the regulating cylinder, and during the time that the engine ceased to act, the weight of the regulating piston forced the air into the furnace. This method of regulating the blast, which continued in general use for many years, has been superseded by the water regulator, and by the double acting blowing cylinder, wrought by a steam engine of Watt and Boulton's construction.

An engine of this kind, of large dimensions, is represented in Fig. 1. of Plate LXIII. It is wrought by a steam engine of thirty-five horse power, with a steam cylinder of thirty-three inches diameter, acting with a seven feet stroke. On the opposite end of the beam from the steam cylinder is jointed the rod D, which is turned exceedingly true, so as to move through the stuffing box without allowing any air to escape, and without any unnecessary friction. A quantity of hemp is placed round the rod in the box *a a*, which forms part of the lid of the cylinder, and is held tight by the iron nuts *b b*. The piston is fitted to the lower end of the rod D, and is packed with leather so as to fill exactly the internal diameter of the cylinder AA. To this cylinder are fixed four necks, B, F, G, H; two of which, B, F, contain the suction valves, by which the air enters the cylinder, while the other two contain the forcing valves, through which the air is expelled at every elevation and depression of the piston into the chambers I, K, and through the pipes L, M, into the regulating receiver OP, which is of the form of a parallelepipedon, or an inverted box without the lid, and is immersed in a cistern RS, filled with water.

Let us now suppose that the piston is at the bottom of the cylinder AA, and begins to be raised by the engine. The air above the piston will obviously be condensed, and forcing open the hanging valves in the neck G, will rush through them into the pipe L, and thence into the receiver OP. While the piston thus rises and condenses the air above it, there is a vacuum below the piston, and the external air rushes through the valves in the neck F, and fills the space below the piston. When the piston descends from the top to the bottom of the cylinder, the air below it is condensed, and forced through the valves in the neck H into the pipe L, and thence into the receiver O P, while the

* Ferguson's *Lectures*, by Dr Brewster. Vol. II. p. 415. See also Lewis's *Commerce of Arts*, the *Journal des Mines*, and Nicholson's *Journal*, Vol. XII. p. 48.

space above the piston is a vacuum, and is instantly filled by the rush of the external air through the valves in the neck B. This operation is repeated at every stroke of the engine; the cylinder-full of air which is inhaled at the necks B and F, being forced through the opposite necks G and H. When the piston reaches the top or bottom of the cylinder, there would evidently be a short cessation in the blast of air that passes into the furnace, were it not for the regulating receiver O P. When the air is forced into this receiver, the water within it is pushed out or displaced, and rises in the cistern, so that the surface of the water in the cistern is often six, seven, or eight feet higher than the surface of the water in the receiver. The air in the receiver, therefore, is pressed upwards by a column of water, six, seven, or eight feet high, so that if there should be any intermission in the supply of air from the cylinder, the blast will be kept up by the extrusion of the air in the receiver. The receiver O P, as shewn in the Figure, is composed of a great number of cast iron plates, united by screws and flanches. Its size in the drawing is purposely diminished, in order to comprise it within the limits of the Plate. The general size is forty feet in length, twelve feet in depth, and twelve feet in breadth. The water cistern is then forty seven feet long, fourteen feet deep, and nineteen feet broad. The receiver is supported upon blocks of wood and masonry; its lower edge being two feet from the floor of the cistern, to allow a free passage for the water. The buoyancy of the receiver is overcome by a great quantity of masonry placed upon the top of it; but we have omitted this in the figure, for the purpose of shewing the manner of uniting the plates of which it is composed.

A valve, loaded with a weight, is placed at T in the horizontal pipe. The weight is sufficient to keep the valve shut when the engine works with a proper velocity; but when it works too hard, the excess of air will escape through the valve. When this happens, the velocity of the engine must be diminished.

The horizontal pipe NM, after bending downwards, is divided into two branches X, Y, which, by a series of pipes, convey the air round the furnace, so as to introduce the blast at opposite sides of the hearth; a practice which is now pretty generally followed.

In the construction of a blowing machine the greatest caution is necessary. The pipes should be carried at such a height above the cistern, that there is no possibility of the water, when at its highest point, being forced through the pipes into the furnace.

The cylinder AA is made of cast iron, with a flanch at each end. The upper necks G, B are cast in the same piece with it, but the lower ones, H, F, are screwed to the under flanch of the cylinder. The valves within the necks B and F open inwards. They are made of leather, covered with plates of iron, and are screwed, by a projecting part of the leather, against the external plate *a* of the chamber, so as to cover three corresponding apertures in the plate (See Plate LXIII. Fig. 2.) *ry*, which is screwed to the neck by a number of bolts, shewn in the Figure. This plate is removed when the valves require any material repairs; but any trifling adjustments may be made, by the workman's thrusting his hand through one of the valves to repair the adjacent one. The plates which carry the valves in the chambers I, K, are not moveable; but apertures are left above to give access to the valves. These apertures,

when the engine is at work, are covered by the lids *h h*, which are fixed down by screws at each end.

The piston is rendered air tight by means of a ring of leather screwed on the upper and one on the under side of the piston, which, in consequence of their elasticity, press gently against the inside of the cylinder. In order to renew these rings when worn out, there is a hole in the lid, and another in the bottom of the cylinder, sufficient to admit a man for that purpose. In some cases a moveable lid is made in the piston.

The cylinder is held down by four large bolts, two of which are seen in the figure at *d d*, passing through a massive pier of brickwork or masonry, sufficiently stable to keep the cylinder steadily in its place. The cistern RS is placed at a much greater distance from the cylinder than is represented in the Figure, lest the tremulous motion produced by the violent concussion of the included air should make the cistern leak. An accident of this nature ought to be carefully prevented; as the water which escapes may insinuate itself into the sand of the casting-house, and occasion the most perilous explosions, when the hot metal is introduced into the moulds.

The internal diameter of the cylinder AA is five feet two inches, and the stroke seven feet. It is capable of blowing one furnace, when working at the rate of six strokes per minute. (q)

BOA, a genus of serpents. See HERPETOLOGY and SERPENT.

BOADICEA, BOUDICIA, or BUNDICIA, a queen of the Iceni, and famous for the formidable resistance which she opposed to the Roman arms in Britain. Prasutagus, the king of the Iceni, had submitted with an unworthy humility to the Roman power, and bequeathed his estates to his two daughters and to the Emperor Nero. In carrying this will into execution, Caius Decianus, the procurator, seized upon all the property of the king. Boadicea remonstrated against this iniquitous proceeding; but her boldness was punished by the most intolerable outrages. The procurator commanded her to be scourged in public as a slave, and her daughters to be violated by his officers.

Exasperated at these unprovoked aggressions, the Iceni rose in arms. Boadicea inflamed their courage by a species of powerful eloquence which she seems to have possessed; and the spirit of revolt, which was kindled from individual wrongs, was speedily infused into the neighbouring nations. The insurgents soon amounted to above 120,000, and began their offensive operations against the Romans. Camalodunum was taken, and the inhabitants put to the sword. The ninth legion was cut to pieces, and Petilius Cerealius, who commanded the cavalry, was compelled to entrench himself in his camp. In order to quell this rebellion, Suetonius Paulinus marched by a dangerous route to Augusta (London); but as he reckoned this post untenable, he retired to unite his scattered forces. The eastern part of the island was now in the possession of Boadicea. The blood of 70,000 of her persecutors had been shed to expiate her wrongs; and her army now amounted to 230,000. Even against this powerful host, Suetonius determined to risk a bat-

le. He waited in silence the approach of the Britons, who began the attack with loud shouts and songs of victory; but the skill and intrepidity of the Romans repelled this furious attack, and gained a great and decisive battle, with the loss only of 400 killed. More than 80,000 of the Britons fell in this engagement, which put an end to the hopes and the power of the insurgents. Dispirited by this irretrievable defeat, and dreading the consequences of becoming a Roman captive, Boadicea either died with chagrin, or ended her days by poison. (A. D. 61.) See Dion. *Hist. Roman.* lib. lxii. cap. 1—12. Tacit. *Annal.* lib. xiv. cap. 31—37. Hume's *Hist. of England*, chap. i. p. 8. (π)

BOADJOOS, a set of itinerant Mahometan fishermen of uncertain origin, who live on the coasts of Borneo, Celebes, and other adjacent islands, in small covered boats, which are managed by the women. Their chief occupation is fishing and making salt, which they obtain from sea-weed. The language of the Boadjoos is peculiar to themselves, but they have no written characters. See Stavorinus's *Voyages*, vol. ii. p. 240. (j)

BOAR, WILD, the *Sus Scrofa* of systematic naturalists. The description and habits of this animal will be found under the article MAMMALIA. In the present article we shall merely give a short account of the method of killing and hunting the boar.

The wild boar abounds in various parts of Europe and Asia, and also in the north of Africa; and in every country that it frequents, it affords a barbarous amusement to the natives.

The best season for hunting boars is between September and December, before they go to rut. The oldest boars are the best subjects for this sport, as they do not run far, and often stop to repel the dogs; while the young boar runs to a great distance, and does not allow the dogs to approach it. As the boar leaves a strong odour behind him, and moves very slowly, trained mastiffs are preferable to fine hunting dogs, which would lose the power of their nose, and acquire a habit of moving slowly. When the dogs are in full chace, the huntsman rides into the middle of them, and impedes and disheartens the boar by charging him with his spear. When the animal finds a place of shelter, he will stand at bay, and attack the dogs as they attempt to seize him. In this situation the huntsmen generally strike the boar with their spear or lance; but this is done with the utmost caution, as he attempts to catch their spear upon his snout or tusk, and often attacks them in the most ferocious manner. The blow is generally aimed between the eyes, or on the shoulder, where it commonly proves fatal. When he attacks the huntsman, he sometimes endeavours to catch the spear in his mouth, and when he succeeds in this attempt, the huntsman will infallibly fall a prey to him, unless another person attacks him, behind. The boar returns upon his second opponent, and is sure to fall under this system of alternate attack. The dogs are sometimes provided with bells round their necks, which often prevent the boar from attacking them.

In the year 1787, a boar of an extraordinary size, near Cognac in Angoumois, resisted all the attempts of the huntsmen, and killed several dogs and men whenever he was attacked. He was at length slain, and several bullets were found between his skin and flesh. See Buffon's *Hist. Nat.* tom. ix.; and Sonnini's *Travels*, p. 348, &c. (j)

BOARDING. See NAVAL TACTICS

BOAT, LIFE. The hazard to which mariners are incessantly exposed, and the helpless condition of mankind struggling with an element speedily destructive of existence, have led to many ingenious contrivances for the purpose of averting danger. Though we cannot but lament that the expedients resorted to have so often proved abortive, we must, in justice to the inventors, maintain, that the want of due deliberation, which, in difficult situations, is generally indispensable to success, has more frequently been the occasion of failure than any imperfection in the expedients themselves. About sixty years ago, jackets covered with cork were adopted; yet notwithstanding the certain and immediate security which, in ordinary cases, the use of them will afford, they are now totally neglected. Cords, in like manner, with buoyant substances affixed, are formed to encircle the body; and a buoyant apparatus has, in the course of last year, (1810,) been exhibited in France, by the aid of which a person can safely advance into the sea, without the risk of sinking. The Chinese, when going on voyages, provide themselves with a very simple means of preservation in the event of shipwreck. This consists of four spars joined together, so as to form a square hollow frame, which being put below the arms, easily supports a person floating in the sea. Recently a gun has been employed to throw a rope ashore, for which contrivance a parliamentary reward has been given; and it certainly promises success, where a vessel is stranded, or is driven towards a steep rocky shore. Nay, it is undoubted, that had the same expedient been tried, where there was full opportunity of doing so, the fatal consequences of many most deplorable shipwrecks might have been averted. But an invention which has proved of infinitely greater utility, in this island at least, is a vessel of a particular construction, called the *Life Boat*.

It is well known, and has long been familiar to seamen, that some vessels of a certain form are better adapted either to keep the sea, to resist the violence of storms, or the pressure of ice; and it has repeatedly been found, that where others sunk, or were over-set, the accident was partly owing to their structure. Examples are commonly given of the Deal boats, and those employed at Madras, of the construction which is best suited to come through the heavy surf beating on an extensive shore; and in different places, the nature of the service to be performed is studied in the structure of the vessel. The wonderful voyages accomplished in open boats, such as those of the Centaur man of war, the Bounty storeship, and the Pandora frigate, proved that safety did not invariably depend on the size of a vessel; and it was thence conceived, that a boat sufficient to extricate shipwrecked mariners from perilous situations, might be navigated by an adventurous crew. But the more immediate origin of the life boat, which we are about to describe, resulted from a dreadful shipwreck in September 1789. A vessel struck on the Herd sands of Tynemouth during a storm; though within 300 yards of the shore, and notwithstanding high rewards were offered, the imminent danger deterred every seaman from going to her relief, and the unfortunate crew dropped one after another from the shrouds into the waves in sight of thousands of spectators. Deeply impressed by this melancholy catastrophe, the gentlemen of South Shields immediately formed themselves into a committee, and offered a premium to any one who should invent a life boat, on such a construction as would be

beneficial in situations of danger. Different models were accordingly framed, which were submitted to the committee; and after due consideration, one invented by Mr Henry Greathead of South Shields received the preference. A boat was soon built on the plan of this model, which first made an attempt in January 1790, that proved completely successful; and since that period thousands of useful lives have been preserved, both in this kingdom and abroad, by others of a similar construction.

This is not the only life boat that has been proposed, nor can we affirm that it is not susceptible of essential improvements; yet, having met with more general approbation, and having been more frequently put to practical use, we shall treat of it in preference to others.

The inventor's attention was originally attracted to the principle on which the life boat is constructed, by observing, as he himself expresses it, "that each part of a spheroid divided into quarters, nearly resembles a wooden bowl having projecting ends. If this be thrown into the sea, or broken waters, it cannot be upset, or lie with the bottom upwards." With these remarks in view, Mr Greathead formed his life boat, the keel being a curved beam, and both the stem and stern raking towards each other.

The size of the life boat is arbitrary, depending on the different service it has to perform; and if certain definite dimensions, such as we are about to describe, be adopted, it is from conceiving them sufficient for the intended purpose, and not by a comparison of the advantages attending life boats of various sizes. The life boat is thirty feet in length, ten in breadth, and in depth, from the top of the gunwale to the lower part of the keel in midships, three feet four inches, from the gunwale to the platform within two feet four inches, from the top of the sterns to the bottom of the keel five feet nine inches. Both ends of the boat are alike, the sterns being segments of a circle, with a considerable rake towards each other. The keel consists of a beam three inches thick, of a proportionate breadth in midships, narrowing gradually towards the ends to the breadth of the sterns at the bottom, and bending with a great convexity downward. The bottom section to the floor heads is a curve fore and aft with the sweep of the keel; the floor timber has a small rise, curving from the keel to the floor heads; a bilge plank is wrought in on each side next the floor heads, with a double rabbet or groove of the same thickness as the keel; on the outside of this are fixed two bilge trees, nearly corresponding with the level of the keel. The ends of the bottom section resemble the lower part of a kind of fishing boat which in Scotland is called a coble; from whence to the top of the stern it becomes more elliptical, and forms a considerable projection. The sides, from the floor heads to the top of the gunwale, flaunch off on each side, in proportion to about half the breadth of the floor. The breadth continues far forward towards the ends, leaving a sufficient length of straight side at the top. The sheer is regular along the straight side, and more elevated towards the ends; the gunwale, fixed on the outside, is three inches thick. From the under part of the gunwale, extending 21 feet 6 inches along the whole length of the regular sheer, the sides are cased with layers of cork, sixteen inches downward, and four inches thick; whence the casing projects a little without the gunwale at the top. The boat is fastened with copper nails, and

the cork on the outside secured with thin plates or slips of copper. There are five seats, or thwarts, double banked, therefore the boat may be rowed with ten oars, and these thwarts are firmly stanchioned. The oars are short, and made of fir of the best quality, which is preferable to any other wood; for experience has proved, that an ash oar, dressed clean and light, is too flexible among breakers, and if strong and heavy the rower becomes soon exhausted. The oars are slung over an iron thole, provided with a grommet, which enables the rowers, merely by facing about, to row either way without turning the boat; a circumstance of infinite importance in broken water. The boat is steered by an oar at each end, one-third longer than the rowing oars; and, for the convenience of the steersman, a platform within, at the bottom of the boat, is horizontal the length of the midships, and elevated at the ends. From the under part of the thwarts down to the platform, the inside of the boat is cased with cork; on the quantity of which, indeed, the chief properties of the life boat, in our opinion, depend. No less than 7 cwt. of cork being used in the construction of the life boat now described, the great specific levity, if we may so express ourselves, will sustain an amazing weight, while the parts of the boat itself hold together. It is not only of great service in keeping the boat in her due position on the sea, but also in creating a tendency immediately to recover from any sudden cant, or lurch, from a heavy wave; and it is, besides, beneficial in diminishing the violence of beating against the sides of the vessel which she may go to relieve. Other important properties have been sought for in the figure and construction of the boat itself; points assuredly meriting the deepest consideration, as they may demonstrate the causes of an unsuccessful attempt, or lead to the formation of life boats on an improved principle. Exclusive of the utility of the cork, it is maintained, that the similarity of the ends of the boat, which admits of her being rowed either way, facilitates her rising over the waves; the curvature of the keel aids her motion in turning, and contributes to the ease of steerage, because a single stroke of the steering oar produces an immediate effect, the boat moving as it were on a centre. When rowing against the waves, the fine entrance below is of use in dividing them; and, combined with the convexity of the bottom, and elliptical form of the stern, enables the boat to rise with wonderful buoyancy in a high sea, as also rapidly to launch forward without shipping water, when a common boat would be in danger of filling. It is said to be proved by experience, that boats of the construction of the life boat, in spreading from the floor heads to the gunwale, are best adapted for rowing against turbulent waves; and that the continuation of the breadth forward, is a great support to her in the sea. When full of water, the life boat is in no danger either of sinking or upsetting, as her internal shallowness, her peculiar figure, and bulk of the cork within, admit but a small quantity of it. These are some of the qualities which are conceived to result from the figure and structure of the life boat, compared with those of the ordinary construction.

The life boat is generally kept in a boat-house close to the beach, where it rests on four low wheels, or trucks, concave, for rolling on oars, or spars laid on the sand, so as to be run out on a moment's notice. But, where the way over which she must be dragged is rough, and the safety of her frame would be endangered, another expedient is adopted. This consists of two wheels.

twelve feet in diameter, with a moveable arched axis, to which a pole is fixed for a lever. The boat is suspended between the wheels, under the axis, towards each extremity of which is an iron pin. When the pole is perpendicularly elevated, the upper part of the axis becomes depressed, and a pair of rope slings encompassing the boat being fixed to the iron pins, she is raised with great facility by means of the pole, which is then fastened down to her stern. There are commonly two crews, each consisting of twelve men, employed to navigate the life boat, to whom rewards are distributed, according to the success of their enterprise.

On the first alarm of a vessel in danger, the life boat immediately puts to sea, when some experienced steady person takes the command. Her head should be kept to the sea, and she must possess an accelerated velocity to meet the wave. Great caution is to be observed on approaching a wreck, where the reflux of the waves is often productive of danger, and it is considered safest to go to the lee quarter. This, however, depends on circumstances.

A life boat, built on the preceding construction by Mr Henry Greathead, the inventor, first went off from South Shields in January 1790, and completely succeeded in bringing the crew of a stranded vessel ashore. After the value of the invention had been acknowledged, by the presentation of a gold medallion to Mr Greathead by the Society for the Encouragement of Arts, as also one by the Royal Humane Society, and various gratuities in money, parliament, on the 9th of June 1802, unanimously voted him 1200*l*. The committee of underwriters likewise at Lloyd's Coffeehouse in London, having voted Mr Greathead 100 guineas, appropriated 2000*l*. of their funds for the purpose of encouraging the building of life boats on different parts of the coasts of the kingdom. Life boats have been sent from Britain, on the order of the Emperor of Russia, who signified his approbation by presenting the inventor with a diamond ring; by the Kings of Prussia, Denmark, and those of other states,

Although the life boat has been successful in innumerable cases, and has been the means of preserving many valuable lives, it has sometimes failed. Of this there was a deplorable instance in last year, 1810. The weather becoming more moderate on the 7th of April than it had been for some time past, induced several fishermen near Tynemouth to launch their boats and put out to sea. But a furious storm suddenly arising, great apprehensions were entertained for their safety, and the life boat was quickly procured, which, amidst a high sea, rowed through the breakers with fifteen men. The fishermen were safely taken on board, and two thousand people were collected on shore, anxiously expecting the return of the adventurers. Some difference of opinion prevailed among the crew of the life boat, regarding the most suitable place at which to land, and the majority determined to push for Hartley Bates, instead of making Shield's harbour, which they could have done within an hour. When nearly in a state of perfect security, a very high wave broke into the life boat, killed or dreadfully maimed the steersman, along with two or three others, and almost stove her in pieces. Nevertheless she continued floating, though her gunwales were level with the broken water; but the crew lost all command of her, and, drifting still nearer the shore, she struck and split asunder. Only two individuals out of twenty-seven, from this unfortu-

nate circumstance, escaped. It is true, that there might here have been mismanagement, but there are situations where the attempts of the life boat may be abortive.

It proves of infinite utility on a sandy beach, but can be less serviceable on a rocky shore. The great weight of this life boat is also a considerable impediment, both to dispatch in getting her out, and to management in a turbulent sea.

Previous to Mr Greathead's invention, a patent was granted to Mr Lionel Lukin, a coachmaker in London, for "an improvement in the construction of boats and small vessels, which will neither sink nor overset." The essence of the invention rests on the property and practice of outriggers, known to all the savages of the South Sea islands. Projecting gunwales are built to vessels of the ordinary construction, sloping from the top of the common gunwale towards the water, so as not to interrupt the oars in rowing; and from the extreme projection returning to the side in a faint curve, at a suitable distance above the water line. These projecting gunwales are very small at the stem and stern, and gradually increase to the requisite dimensions: and they may either be solid, consisting of light substances, of cork, or hollow. In the inside of the vessel at stem and stern, and at the sides where projecting gunwales are unnecessary, as also under the seats and thwarts, are to be inclosures or bulk heads, water tight, or filled with substances specifically lighter than water. "By this means," the inventor observes, "the boat or vessel will be so much lighter than the body of the water it must displace in sinking, that it will with safety carry more than its common burden, though the remaining space should by any accident be filled with water." To give stability to the vessel, the inventor further proposes to affix a false keel of cast iron or other metal along the centre of the real one. The patent granted to Mr Lukin is dated in 1785. We do not discover that he obtained any honorary reward for his invention, but above twenty years later we find a gold medal voted by the Society for the Encouragement of Arts to Mr Christopher Wilson, for a "secure sailing boat, or life boat." This boat, which is called the *neutral built self-balanced boat*, is balanced exactly according to Mr Lukin's device, by empty projecting gunwales. Mr Wilson divides his projecting gunwales into compartments, by which means the failure of one will not injure the others, and is undoubtedly a material improvement.

The Chinese vessels are said to be on the same principle. Instead of a large open hold, as in European ships, there are so many chambers, all water tight, and unconnected with each other, so that a leak springing in one cannot communicate to the rest. There are some peculiarities in the construction of Mr Wilson's boat, in being neither clincher nor carvel built, which enables her to sail quicker; and the oars resting on the extremity of the projecting gunwale, rowing is also more easily accomplished. These gunwales are a foot in breadth; and Mr Wilson affirms, that his boat cannot roll at sea, but must always keep a level position, so far as the surface of the sea will allow. "She may heel, but cannot roll; as the balances (projections) are always ready to catch either way, and the opposite one assists the other by its weight out of water and gravitation; neither can this boat pitch like another, for the balance bodies (empty gunwales) being out of the water, and the breadth of six feet only in the water, it can act with a gravity on the water equal to a boat of the weight

(width) of six feet ; but the resistance of the water upwards equal a boat of eight feet wide." The author of this device is here exactly describing the property of outriggers, to which his reasoning is applicable in respect to the projections. But excepting in the compartments of the hollow gunwales, we can scarcely discern any difference between his boat and Mr Lukin's. An experiment is said to have been made with it in 1806, when eight persons put to sea and rowed through very heavy breakers, during boisterous weather. She shipped very little water, and seemed to promise much utility. But we cannot overlook, on a comparison with Mr Greathead's boat, that the latter, even though shattered, preserves a great degree of buoyancy from the quantity of cork used in its construction ; whereas Mr Lukin's or Mr Wilson's boat in that condition would only have the buoyancy of simple timber. A boat of superior stanchness and strength, devised by Mr Boswell, cannot properly be included under this head, although the principles which he lays down merit consideration, because there is nothing to prevent them from being adopted in a life boat.

Several years previous to 1798, Mr Bremner, a Scottish clergyman in the Orkneys, conceived it practicable to prepare a common ship boat in such a manner, as to be highly useful in cases of shipwreck. The expedient he proposes is, first, to load the bottom or keel with a piece of iron for ballast of three hundred weight. Secondly, to secure a quantity of cork, by lashings, sufficient to render any particular boat buoyant ; or, where cork cannot be procured, to secure in like manner by lashings, two casks in the inside of the bow of the boat, and other two in the stern, which shall have the same effect. In preparing a boat for this apparatus, four ring bolts must be fastened in the inside of the keel, one close to the stem, and another close to the stern, and each of the remaining two a third of the whole length from stem and stern. On the outside of the keel are to be two auger holes, through which ropes lashing the cork may be run and fastened to the ring bolts. "The quantity of cork necessary, which will depend on the size of the boat, is to be made up into several parcels, but none larger than one person can easily manage. Each parcel to be properly secured and numbered, so that the whole may fit and fill up the boat completely in the spaces betwixt the ring bolts fore and aft, as above described ; and to answer the end, it is material that there should be cork enough to rise nearly three feet above the gunwales, so as to form an arch from gunwale to gunwale. The cork being thus laid in the boat, it is to be properly secured, first, by passing a strong rope round all, over the gunwales and through the auger bore outside the keel : as also by passing seizing ropes from the ring bolt in the stem to that next it in the keel, taking care to make as many turns and seizings betwixt these ring bolts as completely to secure the cork from slipping out. The very same thing to be done as to the rope round the gunwales and through the hole outside the keel, with seizing ropes from the ring bolts, to be made aft, or in the stern of the boat." We readily agree with Mr Bremner, that, in ordinary circumstances, a boat provided thus with buoyant substances, will neither sink nor upset ; but the previous condition of three hundred weight of iron for ballast, we acknowledge inspires us with well-grounded apprehension. Neither

is there any thing here to enable the boat to encounter a boisterous sea, which in all life boats we consider an indispensable qualification. The buoyancy of a cargo has preserved many vessels. In the deplorable accident which befel the Guardian frigate, she sunk until her decks were level with the water ; and when all her remaining crew expected to be instantly swallowed up in the ocean, to their inexpressible astonishment she still floated. But the decks of the vessel were strong, and there were empty casks within, which, exactly on Mr Bremner's principle, prevented her from sinking. We doubt not that in smooth water, and in certain cases of shipwreck, a boat provided with cork or casks may be useful ; yet we cannot forget that, without either, some open boats have sailed one, two, even above three thousand miles through tempestuous seas. The Royal Humane Society awarded a premium for this expedient in 1800 ; and the Highland Society of Scotland, to which the model of a boat prepared as above was transmitted, likewise testified their approbation by an honorary remuneration. We believe that more recently, Mr Bremner has submitted his expedient to the Society for the Encouragement of Arts, and that it has met with the like approval, though we are still ignorant of the particulars. The principal inferiority of this and the other life boats, compared with Mr Greathead's invention, consists in their being so much more easily injured, and in their remaining serviceable only so long as entire ; whereas his boat may be grievously damaged, and still bring a crew safe ashore. In studying the best principles whereon a life boat should be constructed, great regard is to be paid to those expedients adopted by shipwrecked mariners, who had few conveniences at command ; and to the causes which have been destructive of open boats or decked vessels at sea. See Greathead's *Report of the Evidence respecting the Invention of the Life Boat. Transactions for the Encouragement of Arts*, vol. x. 20, 25. *Repertory of Arts*, vol. iii. 27. *Transactions of the Highland Society*, vol. ii. (c)

BOCCACIO, or BOCCACE, JOHN, sometimes called JOHN DE CERTALDO, a celebrated Italian writer, was born at Certaldo, in Tuscany, in the year 1513.* Though his father was a peasant with a large family, he resolved to educate him for the mercantile profession ; and, with this view, placed him under a merchant at Florence, who carried him with him to Paris. From his knowledge of accounts he at first gained the affection of his master ; but his taste for poetry began to relax his attention to business, and, after a service of six years, his master dismissed him for negligence. He now began the study of the canon law ; but neither the remonstrances of his friends, nor the hopes of preferment, could induce him to continue a study which was at such variance with his taste for poetry and philosophy. He persevered, however, in his studies till the death of his father, when he abandoned all his professional views, and devoted himself wholly to poetry. He put himself under the instruction of Petrarch, and sought for knowledge from every other master he could procure ; but his small patrimony was insufficient for such expenses, and he was compelled to accept the generosity of Petrarch, who supplied him both with money and books. About this time he met with Leontius Pilatus, a learned Greek of Thessalónica whom he received into his house, and loaded with kindness, and by whom he was initiated into

* Mrs Dobson says, that Boccaccio was born at Paris. *Life of Petrarch*, book iv. 8vo, vol. ii. p. 21.

Greek literature. He heard him read Homer; he conversed with him familiarly for almost three years; and, as Boccaccio himself remarks, "his best memory was unable to retain the infinite number of things he told me, my mind being also perplexed with other cares, had I not committed them to writing." The reputation which Boccaccio soon acquired, in consequence of his intellectual attainments, attracted the attention of the republic of Florence, who honoured him with the freedom of the city, and employed him in many of their public concerns. In consequence of the turbulent state of Florence, which was then agitated with contending factions, Petrarch (1350) withdrew from that city into security and retirement. The republic regretted the loss of this illustrious poet, and commissioned (1351) Boccaccio to negotiate his return; but, instead of succeeding in this attempt, Boccaccio was inspired by Petrarch with the same love of tranquillity, and he henceforth resolved to quit Florence. After having visited several parts of Italy, he went to the court of Naples, where he met with a kind reception from king Robert. Here he fell in love with Mary of Aragon, the natural daughter of that prince, whom he has celebrated under the name of Fiammetta, and from this cause he remained a considerable time at Naples. From Naples he went to Sicily, where he attracted the particular notice of queen Joan. The tranquillity of Florence being in some measure restored, Boccaccio returned to that city. In 1359, he went to visit Petrarch at Milan, and, in consequence of some conversation which passed between them, he resolved to follow a more serious course of life. This resolution was carried into effect in 1361, when he was warned that his life would be short. This warning was given him by Joachim Ciani, a Carthusian friar of Sienna, who came to him at Florence, and requested a private audience. "I came hither," said the friar, "at the desire of the blessed Father Petroni, a Carthusian of Sienna, who, though he never saw you, by the illumination of heaven knows you thoroughly. He charged me to represent to you your extreme danger, unless you reform your manners and your writings, which are the instruments the devil uses to draw men into his snares, to tempt them to sinful lusts, and to promote the depravity of their conduct. Ought you not to blush for such an abuse of the talents God has given you for his glory? What a reward might you have obtained, had you made a good use of that wit and eloquence with which he has endowed you! On the contrary, what ought you not to fear from devoting yourself to lust, and waging war with modesty, by giving lessons of libertinism both in your life and writings! The blessed Petroni, celebrated for his miracles and the sobriety of his life, speaks to you by my voice. He charged me in his last moments, to beseech and exhort you, in the most sacred manner, to renounce poetry and those profane studies that have been your constant employment, and prevented you from discharging your duty as a Christian. If you do not follow my directions, be assured you have but a short time to live, and that you shall suffer eternal punishments after your death. God has revealed this to Father Petroni, who gave me strict charge to inform you of it." Terrified at this solemn admonition, Boccaccio asked the friar how Petroni came to know him; to which Ciani replied, that Petroni saw all this in a vision, and charged him with this and other commissions at Naples, France, and England.

In consequence of this interview, Boccaccio abandon-

ed the study of poetry and the profane authors, and, in opposition to the expostulations of Petrarch, he determined even to dispose of his library. Under these serious impressions, he assumed the clerical habit, and became more regular and circumspect in his conduct. He revisited Naples in 1362 or 1363, and he soon afterwards went to Venice to see Petrarch. In 1365, he was chosen ambassador to Pope Urban V. at Avignon, and in 1367 he attended that Pontiff at Rome in the same capacity. He was appointed to the public lecture on the *Comedia* of Dante, which was then instituted at Florence, and began his labours in October 1373. The bustle of active life, however, was too oppressive for his advanced age, so that he felt it necessary to retire to Certaldo, where he died of a disease in his stomach, on the 21st of December 1375, in the 62d year of his age, and was buried in the church of St James and St Philip.

Boccaccio was the author of numerous works, both in poetry and prose. Though he was ranked in the poetical triumvirate next to Dante and Petrarch, his poetical compositions are feeble and languid. His *Theseide* is remarkable chiefly for the new kind of measure in which it is written. Boccaccio seems to have been sensible of his inferiority as a poet. After having perused the sonnets and songs of Petrarch, he resolved to commit his own to the flames; and in spite of the remonstrance of Petrarch, he actually burnt all his Italian verses.

The elegance and purity of the stile, however, in which his prose compositions are written, amply atone for the defects of his poetry. The most celebrated of his productions is his *Decamerone*, or a collection of an hundred stories, supposed to have been recited in ten days, by a party of ladies and gentlemen, who had retired from the plague at Florence in 1348. This work met with universal applause. It passed through numerous editions. It was translated into many foreign languages; and even Petrarch himself was so delighted with it, as to translate it into Latin, and dedicate the work to Boccaccio. The stories of the *Decamerone* are only partly fictitious. The manners of various classes of society are accurately portrayed; the tricks of the priests are severely exposed; and the absurd doctrines of the Catholic faith are lashed with the same severity. Hence the Roman Catholic writers have charged Boccaccio with impiety and immorality, and his *Decamerone* has been put into the list of prohibited books. Nor is this charge altogether without foundation. The stories are often of such a lascivious and obscene nature, that the French translator, in the edition of 1697, "has taken particular care to regulate the expressions, and to wrap up things in such a manner that the fair sex may laugh at them without blushing." Bayle calls it "a work of gallantry, wherein are to be seen very diverting love adventures, and a great many roguish tricks played husbands."

The other works of Boccaccio are, 1. his treatise *De Genealogia Deorum*, fol. Basil, 1552, with the notes of J. Mycillus; and containing also a *Treatise on Mountains, Rivers, Seas, and Lakes*. 2. *An Abridgment of the Roman History from Romulus to A. U. 724*. Cologn. 1534, 8vo. 3. *De Casibus Virorum illustrium*, beginning with Adam and ending with John king of France. Augs. 1544. This work was translated into Italian, Spanish, English, and French. His Italian works are, his *Il Philocalo*; *La Fiammetta*; *L'Ameto*; *Il Labirinto*

d'Amore; *La Vita di Dante*; which are all written in prose, and, excepting the last, are all romances of an amorous kind, interspersed with poetry. See Fabricii, *Biblioth. BOCCONIA, a genus of plants of the class Dodecandria, and order Monogynia. See BOTANY. (w)

BOCHART, SAMUEL, the most learned writer of his age, was born of a good family at Rouen, in 1599. His father, who was minister of the reformed church at Rouen, paid particular attention to the education of his son, and had the happiness of witnessing his surprising progress in the acquisition of knowledge. He was put under the care of Thomas Dempster, a learned Scotsman, who published a book on Roman antiquities in 1612; and such was the maturity of his genius, that, at the age of twelve, he composed forty-four Greek verses in praise of his master, which were published at the beginning of the book just mentioned. Having gone through a course of philosophy at Sedan, and maintained public theses in 1615, he went to study divinity at Saumur, under Camero; but owing to the civil war, which dispersed that academy, he went with Camero to London, where he appears to have remained only a short time. In 1621, he repaired to Leyden, where he studied Arabic under Erpenius, and formed a particular connection with his maternal uncle M. Rivet, who dedicated to Bochart his *Catholicus Orthodoxus* in 1629. On his return to France, he was appointed to the church of Caen, in Normandy, where his reputation was greatly extended by a long theological controversy which he held with Veron. This theologian having a special mission from the court to dispute throughout the kingdom, challenged Bochart on the 4th of September, 1628, and harassed him in the most importunate manner till the time and place were appointed. This dispute was held in the castle of Caen, before a number of Protestants and Catholics, and in presence of the duke de Longueville, governor of the province, and continued for nine sittings, from the 22d of September till the 3d of October, when Veron was compelled to quit the field. This travelling controversialist, however, claimed the victory; though his ignorance of Greek and Hebrew, and his sophistry and vanity, were completely exposed by his learned antagonist. The high reputation which Bochart derived from this controversy, was greatly increased, in 1649, by the publication of his *Phaleg* and *Canaan*, the titles of the two parts of his *Geographia Sacra*, a work which treats of the dispersion of mankind occasioned by the confusion of tongues, and of the colonies and language of the Phenicians. In the course of his extensive researches, his attention was necessarily directed to many collateral subjects; and had his life been prolonged, oriental literature would have received many important additions from his pen. His attention was attracted to these subjects, while preparing sermons on the book of Genesis. When he came to the second chapter, he was led to explain the situation of the garden of Eden. The following chapter turned his attention to the origin of nations; and many passages occurred, which directed his attention to the animals, plants, and precious stones mentioned in the Bible. On a

branch of this last subject, he published a work at London, in 1663, entitled *Herozoicon, or De Animalibus Sacra Scripturae*. The information which he collected respecting the garden of Eden, the plants, and precious stones, &c. were not in a state fit for publication at the time of his death.

In the year 1652, Bochart was invited to the court of Christina, Queen of Sweden; and, in compliance with the earnest wishes of that illustrious princess, he repaired thither in company with M. Huet, afterwards bishop of Avranches, who composed an elegant poem on their journey, in Latin verse. The caprice and levity of the Swedish Queen, however, did not well accord with the sober gravity of a divine. Bochart did not relish the liberties which she was disposed to take with her literary friends; and he returned to France in 1653. When engaged in a dispute with Huet, at a meeting of the Academy of Caen, he was cut off by an apoplectic stroke, on the 16th May, 1667.

"The learning of Bochart," says Mr Bayle, "vast as it was, was not his principal qualification; he had a modesty infinitely more estimable in him than all his knowledge. And, on that account, he possessed his glory with a great deal of tranquillity, sheltered from those unhappy quarrels, which so many other learned men draw on themselves, by their pride and passionate style."

Besides the works already mentioned, Bochart published a letter, in 1650, *On the authority of Kings, and the institution of Bishops and Priests*; in 1663, a letter to M. Sarran, attempting to prove that Æneas was never in Italy; and a treatise against La Barré, the Jesuit, *On the Toleration of Lutheranism*. The two first of these were published in the edition of his *Geographia Sacra*, printed at Frankfort in 1681. The works of Bochart were collected and published at Leyden in 1712, in three volumes folio, by M. de Villemandy. (o)

BOCNIA, a town in the palatinate of Cracow, in Poland, surrounded with hills, and situated near the small river Raab, which runs into the Vistula. It is celebrated for its salt mines, which were discovered in 1251. The mine is about 10,000 feet long, 750 broad, and 1200 deep. Alabaster, and large pieces of black wood encrusted with salt, are found in it. The salt occurs in veins; and, after being cut into small pieces, is packed up in casks. (j)

BODEGA, the name of a harbour on the west coast of North America. The north point, which consists of low steep cliffs, has the appearance of an island when seen from the south. The land retires to the east, and forms an inlet favourable for anchorage. It is much exposed to the south and south-east winds; and the entrance of the harbour is obstructed by a bank of sand, on which the water is about nine feet deep. The land rises gently from the shore, and is covered with bushes and verdure. The natives were quite inoffensive. The men went naked, while the women wore skins over their shoulders, and about their waists, and were tattooed like the females of the Sandwich Islands. The language which they spoke, was a mixture of Spanish and their own dialect. East Long. 237° 21', North Lat. 33° 21'. See Vancouver's *Voyage*. (π)

BODIANUS, a genus of thoracic fishes. See Ichthyology. (w)

BODMIN, a borough and market town in Cornwall, situated between two hills, nearly in the centre of the county. The town, which has lately been much im-

proved, stands on the northern face of one of the hills, and consists of a single street, unequally paved, and narrow at one end, stretching for a mile from east to west. It was once the principal seat of religion in the district, and is said to have contained no fewer than fourteen churches. The parish church, the only one now remaining, is a large ancient building, consisting of three aisles and a tower. The principal public building is a new county jail and bridewell, begun in 1779, on the plan of Howard. Near the town are some monumental stones, arranged in three circles, called the Hurlers, supposed, by Dr Stukely, to be the remains of a Druid temple. There is here a manufacture of common serges, and a number of dealers in wool, which is washed and combed in the town, and spun in the surrounding parishes. The yarn is sent to Ashburton, and other places in Devonshire. Large quantities of wool are also deposited here for sale. Number of houses 325. Population 2299, of whom 350 are returned as engaged in trade and manufactures. See Polywhele's *History of Cornwall*. (o)

BOECE, or BOETHIUS, HECTOR, a native of Dundee, descended from an ancient family in the shire of Angus, was born in the year 1470. He first studied at Dundee, and then at Aberdeen, where he was afterwards professor. On quitting Aberdeen he visited Paris, and became a student in that university in the college of Montague. This was the commencement of a friendship and correspondence betwixt him and Erasmus, the scholar and the wit, whose letters, addressed to Boethius, are still extant, and sufficiently attest the estimation in which he held his correspondent. Boethius was appointed principal of King's college, which was founded in Aberdeen by Dr William Elphinston, bishop of Aberdeen, about the year 1500. All testimonies agree in the description of his social qualities and literary attainments. Of the latter, indeed, his productions are a sufficiently honourable testimony. They consist of his *Lives of the Bishops of Aberdeen*, three parts of which are given to Elphinston, the founder of his college. This work does not appear to have been publicly commented upon, with much either of praise or of animadversion. But his great production, the history of Scotland, *Scotorum Historia ab illius Gentis origine*, 1526, has been the subject of dispute, strongly seasoned with that bitterness, which is thought to relieve the insipidity of learned disputation. Lloyd, bishop of Worcester, described Boethius as a late romancer. Sir Robert Gordon of Strathgough, with greater decorum of language, condemned him as severely. "To confess the truth," he says, "I dislike Boethius's history. Ignorant of the laws of historical writing, and living in a rude age, he has written what we cannot read without shame." He then notices his stories of Caractacus, the Silures, whom he places in the north, Camelodunum, and the threatening letter of their king to Julius Cæsar; and then asks, "Is not this solemn doating?" Stillingfleet, bishop of Worcester, pronounces, that if Hector Boethius did not forge all the names of the pretended first race of Scottish kings, from Fergus I. to Fergus II., he did insert many things contrary to the ancient mythology in John de Fordon, and filled up the story of those kings, not out of their own annals as far as yet appears, but in a great measure out of his own invention. Boethius, however, has not wanted advocates; of whom the most distinguished were, sir George Mackenzie, in an answer to bishop Lloyd, entitled, *A Defence of the Royal Line of*

Scotland, and archbishop Spotiswood. The archbishop does not scruple to say, that "Boethius is traduced by some of the English writers for a fabulous and partial historian; but they who like to peruse his history will perceive, that this is spoken out of passion and malice, and not upon any just cause." The truth, however, as in most cases of opposing prejudices, probably lies between both. The mind of Boethius was certainly strongly tinged with the credulity of his day; and he has admitted into his history narratives of idle miracles, pretended to have lent their art to signalize every public revolution. He has also brought its authenticity into some suspicion, by the frequent and detailed specimens of oratory which he has thrown into his history. Hence when his friend and panegyrist Erasmus declares, that "he knew not to lie;" if the phrase allowed it, it would be difficult not to suspect the lively reformer of a sly equivoque, admitting only his want of dexterity. Vossius may seem an impartial judge; and he confessed, in his time, that Boethius had mingled many fables with authentic history: and Buchanan owned, that he was not to be excused.

The history is written in a style which has gained it the highest commendations. Erasmus describes the author as a man of extraordinary felicity of talents, and natural eloquence. As a proof that he gave this opinion honestly, (for he sometimes flattered princes,) he gave a catalogue of his own works then published, 1530, in a letter to Boethius; and in another he sent him some poetical trifles, which he did not wish to see the light, with this confidential caution, *Si quid Erasmus amas, cave illius nugas usquam offeras*.

Boethius is thought to have died about the year 1550. Before his death, he added an eighteenth and part of a nineteenth book to his history, which was afterwards brought down to the reign of James III. by Ferrerius, a Piedmontese. Ferrerius, speaking of the eighteenth book, declares, that he has treated of things there in so comprehensive a manner, that he believes no one could have executed the design with more fidelity and life than he has done.

An epigram was written upon Boethius by Humphrey Lloyd, the English antiquarian, which for dulness might be given for his epitaph:

Hectoris historici tot quot mendacia quæris
Si vis ut numerem, lector amice, tibi,
Idem me jubeas fluctus numerare marinos,
Et liquidi stellas dinumerare poli.

This is no more to be accused of wit than that which was written upon his friend and correspondent Erasmus, though its prosody is better. See ERASMUS. (j. m.)

BOEHMERIA, a genus of plants of the class Monœcia, and order Tetrandria. See BOTANY. (w)

BŒOTIA, was an ancient kingdom of Greece; bounded on the east by Mount Citheron, which separated it from Attica; on the south by the gulf of Corinth; on the west by Phocis; and on the north by the strait Euripus, now called the Negropont. This region is now denominated *Stramulipha*; and Thebes, its ancient capital, is known by the modern appellation *Stives*. Adorned by the Copais, a lake fourteen miles in length and eight in breadth, and intersected by the rivers Ismenes and Asopus, as well as by many lesser streams, the valleys of Bœotia were remarkably fertile; and the hills, which were most numerous in the district of Aonia, properly so called, afforded excellent pasturage for

flocks. Washed by the sea on three sides, and indented with many convenient harbours, no country was more adapted for the cultivation of an extensive commerce, and for adding to its natural productions the comforts and luxuries of the various quarters of the globe. The following places, rendered famous either by the poetic or historic muse, were situated in this region. Aulis, a sea-port on the Euripis, celebrated as the place where the Grecian heroes assembled to form that confederacy which terminated in the destruction of Troy. Theſſia, a city built upon the river of the same name, and Mount Helicon, which rises behind it; places consecrated to the muses, and from which that harmonious choir were called Theſpiades and Helicomades. The cave of Trophonius, who, being consulted as a soothsayer by the credulous neighbourhood, gave rise to the fable that Jupiter there uttered his responses, and that the persons who entered the cave to consult the oracle, were never afterwards seen to laugh. The straits of Thermopylae, situated at the foot of Mount Oeta, where Leonidas and the 300 Spartans opposed the vast army of Xerxes, and gloriously perished to save their country from Persian slavery.

When we attempt to form an acquaintance with the first inhabitants of this region, we find them so involved in the darkness of antiquity, that it is impossible to discover their origin, to mark their character, or to describe their exploits. The fabulous muse of Greece informs us, that Jupiter, in the shape of a bull (probably in a ship, which, having that animal painted on its stern, bore that name,) carried off Europa from the court of Agenor king of Sidon to the island of Crete: that her father commanded Cadmus to go in quest of his sister, and not to return till she was found; that Cadmus, after a long and unsuccessful search, arriving at Delphos, in obedience to the oracle, followed the foot-steps of an ox, which was browsing in the fields; and that on the spot where that animal lay down, he built a citadel, which he called Cadmea from himself; laid the foundations of his capital, which he denominated Thebes; and to the country itself he gave the name Bœotia, from the ox (*βουξ*) which had been his guide. The learned, however, are not agreed concerning the country from which Cadmus and his associates migrated. Some think that they were natives of Thebes in Egypt, and that this new capital derived its name from that place; others that they came from Phenicia; but if we durst hazard a conjecture, we would suppose that they were Canaanites, of the family of the Cadmonites, (Genesis xv. 19.) or *Easterlings*, an appellation which they received from their inhabiting Mount Hermon, the eastern boundary of Canaan, from which place Hermione the wife of Cadmus derived her name; and that they fled from the invasion of Joshua, with whom they were cotemporary. It has, however, been maintained, that this region was called Cadmus by Cadmus, and that it received the name of Bœotia long after in this manner: Bœotius, the son of Neptune by Arne the daughter of Æolus king of Æolus in Thessaly, succeeding to his grandfather, called that kingdom Bœotia from his own name, and his capital Arne from the name of his mother. This Bœotia subsisted, as an independent state, upwards of 200 years. At the end of that period, the inhabitants were forced by the Thessalians, to migrate to the country which the descendants of Cadmus still possessed; and obtaining there a settlement, called it Bœotia from the country which they had left.

We, however, imagine that it bore that name from the time of Cadmus. As it is supposed that the rape of Europa took place about 1545 years after the flood, the kingdom of Bœotia must have been founded a short time afterwards. From Cadmus to Xanthus, the last of the Bœotian kings, a period of nearly 300 years elapsed. At his death the Bœotians, weary of kingly government, formed themselves into a republic, which continued till they were subdued by the Romans. But as this dynasty is chiefly known in history by the name of THEBES, we refer our readers to that article for an account of its exploits, both in its monarchical and its republican form.

As written laws, which only can circumscribe the will of the prince and secure the rights of the people, were unknown during the time of the Bœotian kings, a most arbitrary and tyrannic despotism was established. When the kingdom became a republic, the principal officers of state were, the prætor, or strategos, who presided in the supreme council, and had the chief command of the army. The bœotarchi, who formed the grand council of the nation, both in civil and military affairs, and who were empowered, not only to assist the prætor with their advice, but also to compel him to adopt it. The polemarchi, who administered justice in the various districts, and maintained the internal tranquillity of the state. Our knowledge of the Bœotian laws is very imperfect. It appears, however, that though neither merchants nor mechanics were allowed to exercise any office of government, till the expiration of ten years after they had retired from business, yet they were accounted citizens, an honour to which they were not admitted in any other Grecian state: That the parent who exposed his child was capitally punished; and if he was not able to support it, the magistrate had authority to assign it, as a slave, to any one willing to receive it: That marriage was contracted by bringing home the bride in a kind of ear; the axle-tree of which, by being immediately burnt, informed the bride that she was never to desert the house of her husband. Robbery and piracy, which, at least in the early period of the state, were frequently practised, rendered property insecure; and the insecurity of property greatly obstructed the progress of agriculture and commerce. As pride and courage were prominent features in the Bœotian character, we allow, that the former sometimes inspired them with insolence, and the latter degenerated into cruelty; but their history, disfigured as it is by poetic fables, will not allow us to imagine that their annals were stained with deeds of greater atrocity than those which blackened the annals of neighbouring states. When we likewise recollect that the *Sacred Battalion*, a band of 300 young warriors, were raised and maintained and disciplined by this state; that their military evolutions were directed by the harmonious sounds of the flute; that their minds were animated by the most generous and manly sentiments; that their valour often triumphed over the power of Sparta, and at last covered with their bodies the ground on which they were stationed at the unfortunate battle of Cheronæa; we will readily acknowledge, that though the Bœotians might not be free from those vices which universally prevail when civilization is only in its infancy, yet they likewise exhibited, in no common degree, those virtues, which, though they may be softened and refined by art, must derive their origin and their vigour from nature. The men were generally healthy, strong, and active: the women tall, elegant, and beautiful.

ful. Horace asserts, that their minds were rendered dull by their thick and loggy atmosphere. But a country which could boast of that transcendent wisdom and valour which Epaminondas displayed on the fields of Leuctra and Mantinea—a country which inspired the rural lays of Hesiod, which Virgil did not disdain to imitate; and fired the soul of Pindar with those daring numbers, which Horace himself, in the happiest hour of inspiration, could scarcely hope to equal, might bear with contempt the witty sarcasm of that satirist; and we have no hesitation in attributing the little progress of the Bœotians in literature and the fine arts, not to the niggardness of nature, but to the want of proper education, and to their employments, which were better adapted to improve the powers of their bodies than of their minds. Letters, however, were known in Bœotia from the time of Cadmus, though the alphabet which he introduced contained only sixteen characters, and was not completed till many ages after. See Pausan. in *Bœot.* Herod. lib. v. Diodor. lib. iv. Hom. *Iliad.* lib. iii. iv. *Stat. Theb.* Bryant, *Anal. Anc. Myth. Univers. Hist.* vol. ii. p. 370. (S)

BOERHAAVE, HERMAN, a most distinguished physician, was born Dec. 31, 1668. He was son of the Rev. James Boerhaave, minister of the village of Voerhout, two miles from Leyden. Being intended by his father for the church, he was educated on a plan suited to that view, and distinguished himself by his proficiency, both at the public school of Leyden and at the university. When sixteen years of age, he lost his father; and his mother being thus left a widow with nine children, of whom the eldest was not yet seventeen, and with a very slender provision for their support, he found it difficult to obtain the means of prosecuting his education. At one time he was under the necessity of teaching mathematics to procure subsistence. In 1690, he took his degree in philosophy; and in an inaugural disputation on the distinction between matter and mind, he exposed, with great ingenuity and learning, the unsoundness of the principles of Epicurus, Hobbes, and Spinoza. While prosecuting the study of theology, that of nature had not been neglected by him, and at length it seemed to engross his whole attention. He entered, with the concurrence of his friends, on a regular course of medical education, and resolved to obtain a degree in physic before entering the church. Of all medical writers, he particularly admired Hippocrates and Sydenham. The former he considered as the source of medical science; and the latter he says, he repeatedly perused, and every time with greater eagerness. He made rapid and vast progress in all the branches of medical knowledge, anatomy, physiology, chemistry, botany, surgery, and medicine; and obtained a degree from the university of Harderwick in 1693.

But being still resolved to devote himself to the profession of a clergyman, he was on the point of petitioning for a licence to preach, when a report, unjustly spread, of his having revolted to the standard of Spinoza, excited so much popular prejudice against him, that he resolved to abandon his pursuit, and to apply himself wholly to the medical profession.

At first his practice was so small, that it was insufficient for his support; but he continued to supply the defect by teaching mathematics; till, on the death of Drelicourt, in 1701, he was appointed lecturer on the institutes of medicine at Leyden; and was successively professor of physic and botany, and of chemistry and botany, in that university. In 1714, he was made rector

of the university, and physician to the hospital of St. Augustine. The Academy of Sciences at Paris wrote to him about this time, requesting his correspondence on botany and physics, and elected him a member in 1728. The Royal Society of London elected him a member of their body in 1730.

He had filled with such distinction the various offices in which he had been placed, and had acquired so much fame by the publication of his celebrated *Aphorisms*, and other treatises, that Leyden was now become the school of medical science for Europe. Dr Matty says, the city was scarcely sufficient to contain the numbers of students who resorted to him. But in 1722, the course of his academical lectures, as well as his practice, was interrupted by an attack of rheumatism so severe, that the history of it can hardly be perused without horror. He was confined to his bed for five months, and compelled to lie on his back without motion; as the slightest effort gave him exquisite pain. But he at length recovered, beyond the expectation, and to the great joy, of all who knew him.

His malady, he says, was brought on by an imprudent transgression of those rules which he had so often been at pains to inculcate upon others. He rose one morning before light, and rashly exposed himself, while in a profuse perspiration, to the cold air and dews.

His medical skill seems here to have been of little avail; and it is worthy of remark, that his disease had never been described by medical writers as distinct from gout before Sydenham, in whose works only Boerhaave could find an account of his own disorder. It is observable, too, that, in the first edition of the *Aphorisms*, which was published in 1708, no notice is taken of rheumatism; but this disease appears in the subsequent editions; his attention having been but too strongly directed towards it. In the above most distressing, we had almost said scarcely tolerable situation, he set an admirable example of patience and resignation; and this he was enabled to do, not only from his steady acquiescence in the divine principles of Christianity, of which he never lost sight, but also, as he told a friend, from his revolving in his memory, as he lay whole days and nights without sleep, the stores of knowledge he had then treasured up, and thus diverting his attention from what he sometimes thought insupportable torment.

Having resumed his studies and labours, and pursued them with unremitting ardour for four years more, he again became so ill that his friends despaired of him. He recovered, however, so far as to be able to continue his lectures; but, in 1729, having had frequent returns of his disorder, he judged it prudent to resign the professorship of chemistry and botany.

From this time he lived more privately, but was far from being idle. Numerous patients consulted him from all parts of Europe, coming to him when their diseases would permit, and when they would not, transmitting to him their cases in writing, to ask his opinion and advice. Much of his time was also spent in revising his different works for new and improved editions, as well as in revising and publishing correct editions of many valuable works of other writers. Still, however, he enjoyed ease, in comparison of his former mode of life; and he now chiefly resided at his country house, a short way from Leyden, with his wife and daughter, to whom he was greatly attached. His principal amusement was to visit and superintend the culture of the numerous plants in his extensive garden.

About the middle of 1737, he became affected by a disease which at last proved fatal. The following account of which, written by himself to a friend in London, fifteen days before he died, will, we should hope, be acceptable to our readers, not only as a specimen of the manner of this great master of the medical art, but as a historical account of the disease which deprived the world of such a valuable man, and as a proof of his admirable piety and resignation. "*Ætas, labor, corporisque optima finguetudo, effecerant antè annum, ut inertibus refertum, grave, hebes, plenitudine turgens corpus, anhelum ad motus minimos, cum sensu suffocationis, pulsus mirificè anomalo, ineptum evaderet ad ullum motum. Urgebat præcipuè subsistens prorsus et interrupta respiratio ad prima somni initia; unde somnus prorsus prohibebatur, cum formidabili strangulationis molestiâ. Hinc hydrope pedum, crurum, femorum, scroti, præputii, et abdominis; quæ tamen omnia sublata. Sed dolor manet in abdomine, cum anxietate summâ, anhelitu suffocante et debilitate incredibili; somno hæuco, eoque vago, per somnia turbatissimo; animo vero rebus agendis impar. Cum his luctor fessus, nec emergo; patienter expectans Dei jussa quibus resigno data, quæ sola amo et honore unicè.*"

About three weeks before his death he was visited by his intimate friend, the Rev. Mr. Schultens, to whom he said, that, during his long and painful illness, he had had a kind of experimental proof of the justness of the opinion he had always entertained concerning the distinct natures of soul and body, of the thinking and corporeal principles; for though the pains he endured had been long and exquisite, yet they had never been able to oppress him, or prevent the soul from being always master of itself, and resigned to the will of its Maker.

As death approached, he appeared less sensible of pain, and became more cheerful. He expired on the 23d of September 1738, betwixt four and five in the morning, in the 70th year of his age, greatly honoured and lamented.

His conversation towards his last moments was extremely affecting and edifying. He often expressed to the bystanders, how great were now the consolations of divine mercy as offered in the gospel, and particularly recommended to them the observation of that heavenly precept, of love to God and man, so strongly insisted on by the apostle John in his first epistle.

Thus died a man of extraordinary talents and worth, whose fame as a physician and a teacher knew no bounds but those of civilized society; whose genius fixed an era in the history of the healing art; and whose character commanded the veneration of all who knew it. The celebrated Haller, who was his pupil for two years, speaks of him with enthusiasm. "Permit me," says he, "to speak a little more at large of my beloved preceptor, whose erudition some, though few, will equal; but whose divine temper, kind to all, beneficent to foes and adversaries, detracting from no man's merit, and binding by favours even those who were daily objecting to his doctrines and discoveries, will scarcely be paralleled. I attended him," continues he, "from 1725 to 1727, and it is impossible to conceive a more eloquent, easy, and happy manner of expression than he employed." Indeed, the eloquence of Boerhaave was such, that his auditors were always sorry when his discourses were at an end. Original and important views, perspicuously and elegantly expressed, never failed to seize and fix the attention. His method of teaching was most luminous and satisfactory. Pupils flocked to him in crowds

from all parts of Europe, and were not more delighted with his knowledge and eloquence, than won by his affability and attention. He not only guided them in their studies, but consoled them in their distresses, and relieved their wants. When Peter the Great of Russia visited Holland in 1715, he did not neglect to converse with Boerhaave. His fame is said to have extended itself even to the distant regions of China, from whence he received a letter, written to him by a mandarine, and addressed, "To the illustrious Boerhaave, physician in Europe."

Of his astonishing sagacity and penetration in detecting, at the first sight of a patient, such symptoms of disease as no ordinary observer could perceive, instances are related which would be incredible on any other than the most unquestionable testimony: Yet he was so far from presumption, or an overweening conceit of his own powers, that he was remarkably particular in his inquiries concerning his patients; well convinced, that to acquiesce in conjecture where it may be possible to obtain certainty, is either vanity or negligence, and that the man is inexcusable who slights any possible source of information, when the health, or perhaps the life, of his fellow creature is at stake. Haller says he was a successful practitioner, and cured the severest diseases by seemingly simple methods. Though he commenced practice, as we have seen, in very narrow circumstances, he died possessed of a fortune exceeding 300,000*l.* Some have censured him as too parsimonious, but unjustly; for if he indulged not in luxury and expense, it did not arise from parsimoniousness, but from want of time. His avocations allowed him little leisure for the gaieties of life; but he was always liberal when fit opportunities presented themselves.

His habits of life were particularly simple. He rose early, usually at four in summer, and at five in winter, and could not be distinguished by his dress from the plainest citizens. Haller says of him, "*Tædia vitæ tenuitudo consolabatur. Vita ei simplex, calcei in horto lignei, in toto victu exilis, vestituque civis minoris et officis alicujus similem se gerbat.*" His favourite exercise, till towards the latter part of his life, when he became corpulent, was riding on horseback; and when this could no longer be conveniently enjoyed, he spent much of his time in his garden. In personal stature he was above the middle size, robust and athletic in his make, and of great muscular strength. In his air and manner there was something so plain, that it might be almost accounted rough; yet there was, at the same time, something so majestic and great, accompanied by so much good nature, innocent facetiousness, and benevolence, that no man could look upon him without a mixed sentiment of love and veneration. Though grave and serious, he was fond of pleasantries, and both in his private conversation and public discourses used occasionally to indulge in a strain of delicate, good-humoured raillery, in so much, that his manner has been compared to that of Socrates, whose bust he is also said to have resembled in features. He was modest, but not timorous, and always cheerful. Calumny and detraction (which sometimes assailed even him) he never thought it necessary to refute, nor could they ever fret or sour his temper. He said they were sparks, which would go out of themselves if you did not blow them, and that the best way to get the better of malice, was to *live it down*.

Being one day asked by a friend, who admired his patience under great provocation, whether he knew

what it was to be angry? He replied, with the utmost sincerity and frankness, that he was naturally of an irascible temper, but had attained this command over himself by reflection and prayer to God. He was indeed, an admirable example of every moral and Christian virtue. Through his whole life he made it a rule to dedicate the first hour after he rose in the morning to religious retirement. Thus, he said, gave him vigour through the rest of the day, and enabled him to support the fatigues of his profession: For the tranquillity of the mind, he averred, was necessary to the health of the body, and could be maintained amid the distresses of life only by a well-grounded hope of the approbation of our Maker on Christian principles.

Aware that many great men had injured the reputation, and lessened the utility, of their writings, by inattention to the graces of style, he made eloquence and poetry a principal object of study; and was a no less elegant scholar than a profound and ingenious philosopher.

His funeral oration was pronounced by his friend Schultens, and the city of Leyden erected an elegant monument to his memory, in the church of St Peter, with this inscription: *Salutifero Boerhaavii genio sacrum.*

He married, in 1709, Mary Drolenveaux, only daughter of the burgomaster of Leyden, by whom he had four children; three of whom died in their infancy, and the other, Joanna Maria, survived her father.

His genuine works, according to his own catalogue of them, and he declares, in 1732, that all others under his name are spurious, except some prefaces to new editions of books, are as follow: *Oratio de commendando studio Hippocratico*, 1701. *Oratio de usu ratiocinii Mechanici in Medicinâ*, 1703. *Oratio qua refurgata Medicinæ facilis asseritur Simpllicitas*, 1709. *Oratio de comparando certo in Physicis*, 1715. *Oratio de Chemiâ erroris suos exurgente*, 1718. *Oratio de Vita et Obitu Clarissimi Bernardi Albini*, 1721. *Oratio quam habui quum, honesta Missione impetrata, Botanicam et Chemicam Professionem publicè puerem*, 1729. *Oratio de honore Medici servitute*, 1731. *Elementa Chemiæ quæ anniversario labore docuit in publicis privatisque scholis Hermannus Boerhaave*, 1732. *Institutionis medicæ in Usus Annuæ Exercitationis domesticos*, 1728. *Qui dein auctior aliquoties recusus*, in 8vo. *Aphorismi de cognoscendis et curandis morbis, in usum doctrinæ domesticæ*, 1709. *Qui dein aliquoties recusus*, in 8vo. *Index Plantarum quæ in Horto Academico Lugduno Batavo referuntur*, 1710, in 8vo. *Libellus de Materiâ Medicâ et Remediorum formulis*, 1719. *Index alter Plantarum quæ in Horto Academico Lugduno Batavo aluntur*, 1720, in 1to. *Atrocis nec descripti prius morbi Historia, secundum medicæ artis Leges conscripta*, 1724, in 8vo. *Atrocis rarissimique morbi Historia altera*, 1728, in 8vo. *Tractatus medicus de Luc Aphrodisiacâ*, 1728, in folio. His three principal works are, his Institutes, his Chemistry, and his Aphorisms; particularly the latter, which is perhaps more useful than any other book that has ever been written on the subject of medicine. He himself calls it "*libellum mole parvum, gravem materiæ, nec sine labore natum*;" and it is said to have had the honour of being translated even into the Arabic, and circulated in the Turkish empire. See Haller's *Biblioth. Med. Pract.* 1788. H. Boerhaavii *Op. omnia Med. Veneticis*, 1757, Math. Matty, *Essay sur le caractère du grand Médecin, ou éloge critique de H. Boerhaave*, 1747. Hutchinson's *Biograph. Med.* 1799. (z)

BOERHAVIA, a genus of plants of the class Monandria, and order Monogynia. See BOTANY. (70)

BOERO, BUERO, BURRO, BUURO, or BOUKRO, the name of one of the Molucca islands, situated between Celebes and Ceram. It is about 54 miles long from east to west, and 40 from north to south, and was once subject to the king of Ternate. Cajeli, the capital, is situated at the bottom of a gulf of the same name, in a marshy plain, extending about four miles, between the rivers Soweil and Abbo, the latter of which is always turbid, and is the principal river in the island. The island is inhabited by Moors and Alfourians, the former of whom are strict Mahometans, and the latter a free people, who inhabit the inaccessible mountains in the interior. The Dutch company obtain from this island only black and white ebony, and other kinds of valuable wood. The other productions of Boero are pepper, cocoa nuts, bananas, shaddocks, lemons, citrons, bitter oranges, &c. The country is infested with enormous serpents, and with a smaller species of snakes. The rivers swarm with huge crocodiles, which often devour both men and beasts. The Fort of Defence is protected by a garrison of 25 men. See Bougainville's *Voyage.* (11)

BOLTHIUS, FLAVIUS ANICIUS MANLIUS TORQUATUS SEVERINUS, the most eminent of the later Romans, was born at Rome about the year 470, and flourished in the reigns of the Emperors Zeno and Theodoric. He was deprived of his father at an early age, and thus succeeded to the patrimony and honours of a family so illustrious, that even kings and emperors ambitiously assumed its name. Several years of his youth were spent at Athens, where he prosecuted his studies under the direction of Proclus with such indefatigable assiduity, as to make himself master of all the learning of the age. His sound and vigorous judgment preserved him from the affectation of mystery and magic, which then disgraced the Grecian schools; but he caught the spirit, and imitated the example, of Proclus and his predecessors, who endeavoured to reconcile the nervous sense and acute subtlety of Aristotle with the sublime but fanciful contemplations of Plato. On his return to Rome, he continued to pursue his studies with an eagerness unabated by the splendour and the numerous avocations of his exalted situation; and soon gave proofs, in various publications, of the extent of his erudition, and the amazing versatility of his genius. His first work appears to have been a defence of the orthodox creed against the Arian, Eutychian, and Nestorian heresies; and he afterwards published a formal treatise upon the Trinity, which abounds not only with philosophical terms, but with metaphysical subtleties. Boethius appears to have been the first who employed the Aristotelian philosophy to explain the mysteries of religion: a plan which was afterwards very eagerly adopted by the school divines, and which, in their injudicious hands, became the source of such endless wrangling and error, as completely destroyed the spirit, and clouded the beauty, of the mild and pure religion of the gospel.

His next object was to make his countrymen acquainted with the arts and sciences, which had long flourished, though they were now on the decline, in Greece. With this view he translated, and illustrated by commentaries, the geometry of Euclid, the music of Pythagoras, the arithmetic of Nicomachus, the mechanics of

Archimedes, the astronomy of Ptolemy, the theology of Plato, and the logic of Aristotle: "And he alone," says Gibbon, "was esteemed capable of describing the wonders of art, a sundial, a water-clock, or a sphere which represented the motions of the planets." In the midst of these important studies, Boethius never forgot his more essential duties as a citizen, and master of a family; his coffers, almost inexhaustible, were ever open for the relief of the indigent; and his eloquence, at that time unrivalled, was uniformly exerted in the cause of innocence, humanity, and justice. He now saw himself in possession of every thing requisite to his public respectability and private happiness. Allied by birth to the first nobles in the empire, his family grandeur was increased by his marriage with the daughter of Symmachus, who possessed every quality that could give pleasure to the nuptial union. His dignity and his acquirements well entitled him to aspire to the highest offices in the state; and his claims were felt and recognised by the Emperor Theodoric. He was exalted to the rank of consul and patrician: the important station of master of the offices, gave an honourable and useful employment to his talents; and when his two sons had grown up to manhood, he enjoyed the singular satisfaction of seeing them united in the consulship.

Universally esteemed and respected, caressed by his sovereign, and adored by his dependants, one circumstance alone threw a shade over his happiness, and at last completely reversed the fair scene which we have described. With the generous and independent spirit of a Roman patriot, Boethius could not see without deep regret the misfortunes of his country, ruled by a foreigner, and oppressed and insulted by barbarian conquerors. His authority had often checked the pride and tyranny of the royal officers; and his influence had rescued Paulianus from the dogs of the palace. The provincials, whose fortunes had become the prey of public and private rapacity, had often been relieved by his generosity; and he was the only person who was bold enough to oppose the insolence of the barbarians, elated by conquest, excited by avarice, and encouraged by impunity. "In these honourable contests," says the historian quoted above, "his spirit soared above the consideration of danger, and perhaps of prudence; and we may learn from the example of Cato, that a character of pure and inflexible virtue is the most apt to be misled by prejudice, to be heated by enthusiasm, and to confound private enmities with public justice."

When age had converted into a tyrant the wise and tolerant Theodoric, Boethius magnanimously resolved that he would not be degraded to the condition of a slave, and opposed, without fear, the sullen barbarian, who thought the safety of the senate incompatible with the stability of his throne. When the senator Albinus was accused, and already convicted of *hoping* the liberty of Rome, the eloquence of Boethius, animated by all the warmth of friendship and patriotism, was exerted in his defence. "If Albinus," he exclaimed, "be guilty, the senate and myself are all guilty of the same crime. If we are innocent, Albinus is equally entitled to the protection of the laws." If merely to hope for the liberty of Rome was criminal in the eyes of the tyrant, Boethius could not fail to incur his mortal resentment by the less equivocal avowal, that if he had known of a conspiracy, Theodoric never should. He was accordingly involved in the same charge with his client Albinus; their signature, which they denied as a forgery,

was exhibited in the senate, affixed to the original address inviting the Greek emperor, Justin, to deliver Italy from the dominion of the Goths; and Triggilla, Congiastus, and Cyprianus, persons of the most infamous character, though of high rank, were suborned to attest the treasonable designs of the patrician. The senate, overawed by the power of the tyrant, yet unwilling too severely to condemn the most respected and illustrious of their members, pronounced against him a reluctant sentence of banishment; while Boethius, lamenting the servility and degeneracy of his countrymen, predicted, that none, after him, should be found guilty of the same offence. He was conveyed to the tower of Pavia, where he was closely imprisoned and loaded with fetters, expecting every moment the fatal mandate of his sovereign. It was in this dismal situation that he experienced the chief advantage of those studies to which he had devoted his youth. He beguiled the tedious interval between his imprisonment and death, by composing the *Consolation of Philosophy*, an incomparable treasure of sublime and delicate moral sentiments, but still more admirable, considering the barbarism of the age, and the situation of the author when it was written, for the classical purity and elegance of its style. The most judicious critics have not hesitated to compare the *Consolation of Philosophy* with the happiest productions of Plato and of Tully; and Bertius, one of the editors and commentators of Boethius, in a still loftier strain of panegyric, endeavours to account for the superior excellence of this performance by supposing, that, as men approach nearer their death, they feel something divine within them, and passing beyond the ordinary limits of mankind, speak, see, and think much nobler things than they could ever do before. This work, written partly in prose, and partly in verse, is thrown into the form of a conference between the Author and Philosophy, who endeavours to soothe him in his afflictions. He begins by complaining of the miserable state to which he is reduced, when his divine instructor, to assuage his distress, reminds him of the instability of fortune, and of the large portion of happiness which he had so long enjoyed. Yet the supreme good, she assures him, consists not in the wealth, the honour, or even the safety which he had lost, but in the enjoyment of God alone. Hence it follows that the good alone are in possession of real happiness; and although the wicked may often enjoy apparent felicity, and the virtuous may sink in occasional distress, this is only the natural result of the moral government of the Deity over beings free and accountable, whose actions and motives he now watches attentively, and whom he will afterwards equitably judge, to reward and punish them according to their deeds.

About a year, or somewhat more after his confinement, the messengers of death were dispatched by Theodoric, to terminate the sufferings of the virtuous and heroic sage. The manner of his execution is variously recorded. According to some historians, he was beheaded: but others inform us, that a strong cord was fastened round his head, and forcibly tightened till his eyes almost started from their sockets; and that, in this agonising state, he was beaten with clubs till he expired. Thus perished Boethius; a man against whom calumny has been able to allege nothing worse than a generous indignation against the oppressors of his country, and a patriotic eagerness for its liberty. "With Boethius," says Mr Harris, "the Latin tongue, and the last remains

of Roman dignity, may be said to have sunk in the western world;" yet his genius survived to diffuse a ray of knowledge over the darker ages of the Latin world; and his virtues and sanctity were supposed by his credulous admirers to be honoured by the testimony of a miracle at his death. No author has ever been more popular than Boethius, especially before the revival of literature had restored to light the productions of the happier ages of Greece and Rome. His *Consolation of Philosophy* was translated by two of the most illustrious monarchs that ever filled the British throne, Alfred and Elizabeth. Chaucer translated it into prose, and a

verse translation of it was printed in the monastery of Tavistock, in Devonshire, in 1525. It was likewise translated into English by Sir Richard Graham, secretary to King James II. who was committed to the Tower on a charge of high treason in 1690, and suffered a tedious imprisonment. His translation was printed at London in the year 1695. See Gibbon's *History*, vol. vii. p. 42—50. Enfield's *Lives of the Philosophers*, vol. ii. Le Clerk's *Biblioth. Chois.* tom. xvi. *General Dictionary*, vol. iii. (k)

BOG. See DRAINING.

BOGOTA. See SANTA FE DE BOGOTA.

BOHEMIA,

A kingdom in Europe, forming part of the Austrian dominions, and bounded on the west by part of the electorate of Saxony, the principality of Culmbach, and the Upper Palatinate; on the north by Misnia, Lusatia, and Silesia; on the east by Moravia, Silesia, and the county of Glatz; and on the south by Austria and Bavaria. It stretches from 48° 30' to 51° 5' N. Lat. in an oval figure of about 951 geographical square miles.

The whole country resembles an immense basin or concavity, and its bottom forms a plain considerably elevated above the level of the sea. It is surrounded on every side by high mountains; on the north-east by the Sudetes mountains, and the Riesengebürge; on the south-east and south, by the mountains of Moravia; on the west, by the Bohmerwaldgebürge, (Lat. *Sylva Gabreta*, or *Hercynia*); and on the north, by the Erzgebürge. A very considerable portion of these mountains is composed of the first or oldest granite formation, on which rest gneiss, mica slate, clay slate, various porphyries, and other primitive rocks; and these are covered with flætz sandstone, limestone, and various rocks of the newer trap formation. Even the highest summits of the Bohmerwaldgebürge are covered with a kind of brushwood; but the elevated parts of the Riesengebürge are almost bare, and, in sheltered hollows, snow remains during the whole year. The loftiest and most naked branch of this chain is called, in German, Riesengebürge, the mountains of the giants. The Sudetes resemble an immense rampart, surmounted by a train of other ramparts, placed almost transversely. Their principal masses are composed of granite, round which, as a nucleus, are formed strata of porphyry, and mica and clay slate. On the southeast the granite disappears, and the mountains dwindle. This intermediate chain, which connects the Sudetes with the Carpathian Alps, is called by a general name Moravian Hills, or Gezenkergebürge, lowered mountains. The mountains of Carlsberg and Maunhast gird Bohemia on the south, and touch, on the west, the hills named the Forest of Bohemia, (Bahmer Wald,) which are much less elevated than the Sudetes, and are clothed with verdure almost to the summits. At the western extremity of Bohemia, the Fichtelgebürge, or mountain of pines, rises to the height of 3630 Rhenish feet, and forms a common centre to the three chains which separate Franconia from Saxony, as well as Bohemia from Saxony and Bavaria. The Fichtelberg is an assemblage of mountains, precipices, shelves, and ravines; and on the summit there was formerly a lake, now converted into a marsh. Be-

tween Saxony and Bohemia, run the mountains named Erzgebürge, or metallic mountains, which join the Sudetes in Lusatia. On the side of Saxony, these mountains rise to the height of 3600 or 3700 feet above the level of the sea. On the side of Bohemia, they present a great number of peaks composed of basalt, whose imposing aspect adds greatly to the beauty of this picturesque country.

Among the natural curiosities which here present themselves, none is more remarkable than the labyrinth of rocks, near Adersbach, in the circle of Koenigin-groetz. Innumerable rocks of freestone, placed perpendicularly, from 100 to 200 feet high, and of a circumference equal to half their height, forming thus great square towers, occupy a space of a league and two thirds in length, by half a league in breadth. The entrance into this immense group resembles that of an amphitheatre; the verdure of scattered trees and shrubs forms a striking contrast with the grey masses of rocks, the figures of which are fantastically varied. Through the midst of this singular scene winds a pleasant rivulet, which soon dashes into a grotto, where terror seems to reign. The echo of a thousand rocks reverberates the roar of this stupendous cascade.

Bohemia is so much elevated above the level of the sea, that all its rivers take their rise either in it, or immediately on its borders. Its principal river is the Elbe, (*Albe* of the mountaineers, *Labbe* of the Bohemians,) which rises from the western acclivity of the Weissen Wiese, (white meadow,) at the foot of the Schnee Koppe (snow cap,) near to the Silesian frontier. It flows first southwards, then makes a great turn westwards, when it reaches nearly the middle of Bohemia, and from thence it flows northwest towards the Erzgebürge, through which it forces its way into Saxony. The principal tributary rivers are the Aupa, Erlitz, Orlitz, Dabrowa, Iser, the Moldau, which is the second principal river of the kingdom, and the Eger. The Elbe, with the accumulated waters of all these rivers, escapes from Bohemia at Winterberg, near Schandaw. As the opening through which the river forces its way is not only narrow, but bears evident marks of a great rent, and as the whole of Bohemia is surrounded by lofty ranges of mountains, it has been conjectured by the celebrated German mineralogist Werner, that this kingdom was formerly a great inland sea, or lake, in which was collected all the water from the surrounding mountains; that the water of this vast lake, or sea, had forced its way through the bounding rocks at the lowest point at Winterberg;

and thus emptied itself, and formed the narrow rocky ravine through which the Elbe now flows in passing out of Bohemia into Saxony.

No country in Europe can boast of a finer climate than that of Bohemia. Italy itself has not a more delightful spring; and summer and winter, without ever prevailing here in their rigour, only introduce an agreeable variety of season. The mountains, which surround it on all sides, shelter it from every wind; and it is refreshed and beautified by several considerable rivers, the flow of which is so much facilitated by deep cavities in the middle of the vale, that no lakes or marshes are formed, to taint, by their malignant vapours, the salubrity of the air.

The excellence of the climate is equalled by the fertility of the soil. Every thing which can contribute to the comfort, and even pleasures of life, is here produced in abundance. Besides supplying its own numerous population, Bohemia exports great quantities of grain to Silesia, Saxony, and Austria. The crop in 1794 amounted to 24,012,507 measures of corn. Buckwheat, millet, pulse of different kinds, and exquisite fruits, are almost the spontaneous production of this generous soil. It is particularly remarkable for cherries of a very large size and delicious flavour; but almost every kind of fruit grows there in great perfection. In 1786, the number of fruit trees throughout the kingdom amounted to 7,649,489. Its mountains are covered with pines, firs, and various other species of trees; and the interior of the country is adorned by magnificent forests of oak. The aggregate extent of its woods in 1786 was not less than 7,700,000 feet, from which 2,164,174 fathoms of timber may be cut annually. Vineyards have not been cultivated in Bohemia with that diligence which the excellence of the soil and climate seems to invite. The annual produce of its vineyards is estimated at 26,326 eimers, and its most esteemed wines are those of Melnik and Podskalky. Saffron, ginger, calamus, and foxtail, are likewise produced in Bohemia in considerable quantities; but the favourite crop of this country is hops, which grow here in great profusion, and are altogether unequalled in the excellence of their quality. Its cattle, though not very numerous, are of the finest kind: in 1798, their number did not exceed 805,611. Its breed of horses, too, is uncommonly valuable; and in 1793, their number amounted to 130,774. The breed of sheep in this country, though originally of an inferior kind, has of late been much improved. Their number, in 1793, was 2,095,693, yielding annually 40,000 quintals of wool. The annual crop of hay is estimated at 8,101,799 quintals or hundred weight. Great herds of swine are reared in Bohemia, as well as numerous flocks of swans, ducks, and hens. Several thousands of cocks are annually exported into the surrounding provinces. The pheasants of this country are the most beautiful in the world. Its forests and mountains abound with the most interesting species of wild fowl and of game; wild boars, hares, wolves, bears, lynxes, foxes, badgers, beavers, otters, and martins; and its rivers and ponds swarm with various kinds of excellent fish.

Yet the bounty of nature is here but little seconded by the industry of man. The degrading and oppressive system of villainage damps every exertion of the peasant, and deprives him of all interest in the improvement of fields, the fertility of which, instead of multiplying his own comforts, only pampers the luxury of a haughty lord. Nothing can be more wretched than the

condition of the peasantry in Bohemia. Their dwellings are mere ruins, which afford them scarcely the slightest shelter from the wind, the rain, and the cold. To each of these wretched abodes is allotted a piece of ground, with a cow or two, a pair of oxen, or a work horse. Their lords demand from them the labours of the whole week, allowing them only Sunday for the cultivation of their own little spot. In these circumstances, it cannot be wondered that Bohemia should be in general under the worst cultivation, and that even in this fertile country the scourge of famine should be occasionally felt. To prevent the recurrence of this evil, magazines of provisions have been established in various parts of the kingdom, from which, in cases of scarcity, the inhabitants receive the necessary supplies of food for themselves and their cattle.

If it be admitted as a general fact, that the mineral riches of a country correspond to the sterility of its surface, Bohemia at least must be allowed to be a remarkable exception; for while the fertility of its soil can scarcely be surpassed, its subterraneous treasures are likewise extremely valuable. Mines of gold have been found in various parts of the kingdom, but they are too scanty to be wrought with any advantage. Some rivers, too, wash down particles of that metal, but in very small quantities. The silver mines, which are pretty numerous in Bohemia, are richer and more profitable. The richest were those of Kuttenberg, but they are now undated. There is one of considerable importance at Joachimsthal, where the counts of Schlik ordered crown pieces to be struck for the first time in 1619; and others less considerable are found in the circles of Pilsen and Bechin, as well as in the district of Elnbogen. The produce of these mines is about 2400 marks, of eight ounces, annually. Mines of iron are disseminated throughout the whole of Bohemia, and yield annually 193,400 quintals. There is an excellent copper mine in the district of Elnbogen; and the lead mines give about 6000 quintals a year. The copper of Bohemia is very frequently, and the lead always, mixed with a little silver. The tin of Bohemia is, next to that of England, the most valuable in the world; and its tin mines, besides the importance which they derive from their intrinsic excellence, are remarkable as being the termination of the tin mines in the east of Europe; nor are any found farther east till we reach Sumatra and Japan. There are ten mines of this metal in the circle of Saatz, and two in the circle of Leutmeritz; and these are sufficient for the supply of all the Austrian dominions. The net produce of all these mines, without including the iron, is estimated at one million of florins of Vienna. Cobalt abounds in various parts of the country; and its annual produce, which is at present about 11,000 quintals, might be much increased if the demand for it were greater.

There is abundance of zinc, arsenic, and calamine; some antimony, manganese, and bismuth. Mercury is found at Beraune, but in too small quantities to compensate for the expense of working it. Among the minerals in Bohemia we may likewise reckon sulphur and vitriol; and alum is so abundant, that 3500 quintals of it are sold annually for about 36,000 florins. Black coal (pitcoal) and brown coal are in several places, and likewise porcelain clay, and limestone. There are likewise rich quarries of beautiful marble, especially at Tesin in the circle of Beraune. Jasper is found in considerable quantities, as well as alabaster, asbestos, ser-

pentine, and other minerals of a similar kind. Several gems are found in Bohemia, viz. sapphire, topaz, precious garnet, hyacinth, and pyrope. The sapphires are small and of but little value; the topazes scarcely equal those of Saxony; the precious garnet has a good fire and water; the hyacinths are small, and not fit for the purposes of jewellery; and the pyrope, (the *carbo pyropus* of the ancients,) is remarkable for its fine deep blood-red colour and great transparency, and is in high estimation. Very fine agates occur in various parts of Bohemia. In regard to the rocks of this country, we may remark that it contains nearly all those enumerated and described in the Wernerian geognosy. Pearls are fished in the stream of Waltava, and mother-of-pearl is found near Budweis, in the circle of Bechin. Bohemia is likewise celebrated for its mineral waters, which not only attract a multitude of strangers, but are conveyed to every part of Germany.

Before the peace of Hubertsburgh, which was concluded in the year 1763, the manufactures of Bohemia were very inconsiderable: but since that era they have improved so rapidly, that foreign articles are almost wholly excluded from the Bohemian market by the cheapness and superior quality of those fabricated at home. Bohemia is particularly celebrated for its hardware, woollen and silken stuffs, and glass of a very fine quality. Its pottery, too, is excellent; and its paper works, which have the advantage of uncommonly pure water, produce paper of the best colour and texture, both for writing and printing. This country excels likewise in its manufactures of delf ware, composition stones, mirrors, needles, fire-arms, tinwork, hats, (made chiefly of the fur of hares,) gloves, stuffs, stockings, all kinds of jewellery, laces, cambric, and linen. An accurate idea of the manufactures of Bohemia may be formed from the following statement. In 1801, it contained 321,720 spinners of linen thread, and 85,335 manufacturers of linen cloths, ribbands, &c. who were employed at 41,142 looms: the produce of their industry amounted to 9,810,900 pieces of linen, the value of which was about twenty millions of florins. The manufacture of lace employed 16,295 persons, and 1302 were engaged in making veils and cambric. There were 1686 bleaching greens for thread, and 1150 for linen. At the same time this country reckoned 50,614 spinners of wool, 24,563 manufacturers, and 1128 venders of woollen cloth: the value of this manufacture amounted to eight millions of florins. The cotton manufacture employed 31,902 spinners, and 8769 weavers, who wrought at 5830 looms. The town of Prague alone fabricated, at 350 looms, 12,000 dozens of pairs of stockings; the circle of Burz'aw 1650 dozens. There were 360 manufacturers of silken stuffs, who had 166 looms; 630 manufacturers of silk ribbands, and 483 looms; so far back as 1782, there were 70 looms for silk hose, and 111 manufacturers. The whole of the silk manufacture was estimated at 448,260 florins. There were at the same date (1801) 782 paper-makers, who made paper to the value of 181,000 florins; besides a great quantity of pasteboard, parchment, and cards. In 1796, there was sold leather to the value of 915,555 florins, and gloves to the value of 85,000. In 1801, there were 179 forges for iron work, which employed 2517 persons; twelve wire manufactures, in which there are 295 artisans; two manufactures of fire-arms with thirty workmen and sixty-two forgers; thirty-five forgers of scythes, 125 armourers, fifteen file-makers, 382 nailers, and six-

ty-three cutlers. In the same year, the number of glass works in Bohemia amounted to 78; which employed 1821 workmen. The value of the glass vessels annually exported to Spain, America, Russia, and the Levant, is estimated at two millions and a half of florins. Besides these works, there are six manufactures of mirrors, in which are employed 282 workmen; the sale of the two manufactures at Pirstein amounts annually to about 60,000 florins. The composition stones of Turnau employ 139 workmen, and bring in 40,600 florins a year. The two manufactures of granates at Blaskowitz and Swietla bring in only 3000 florins. The manufacture of white starch and hair powder brings in 123,680 florins. There are fifty gold and silver smiths, the value of whose workmanship does not exceed 140,000 florins. For copper work there are eleven forges, and for brass there is one forge and fifty-four workmen; the value of this manufacture amounts to about 140,000 florins. The founderies which supply the whole empire with artillery and bells, are in Bohemia and Lower Austria. The value of the tin manufacture may be estimated at 56,100 florins annually. Of smalt there are eight manufactures, which export to the value of 72,000 florins; there are likewise manufactures of sulphuric acid, which bring in about 13,884 florins.

There are few countries where the balance of trade is more favourable than in Bohemia, for its commerce consists almost entirely of exportation. Besides the cheapness and excellent quality of its home manufactures, the commerce of importation is extremely limited in this country by the want of capital, and the severe prohibition against the introduction of foreign commodities, or the heavy duties to which they are liable. There is one circumstance, however, extremely prejudicial to the interests of the natives; and that is, the disproportionate number of Jews, and, in some districts, of Greeks and Armenians, who have engrossed almost all the trade of the country. "It is a demonstrable and notorious fact," says Schreyer, in his work on the commerce and manufactures of Bohemia, "that in every town, and in every place where the Jews are established, the Christian tradesmen are reduced to the most wretched condition, and that the Jews have enriched themselves at their expense." The countries with which Bohemia carries on the most extensive traffic, are Austria, Spain, Portugal, Italy, and Turkey. Of the quantity and value of its trade, some idea may be formed from the statement which we have already given of its manufactures. The superior elegance which the Bohemians have attained in cutting and polishing flint-glass, occasions such a demand for their glass vessels, that they are sent not only to most of the European nations, but even to America.

The administration of commerce in Bohemia is entrusted to a chamber of commerce, resident at Prague, and subordinate to that of Vienna. This chamber consists of a president, who is, at the same time, a privy counsellor, of six counsellors, and some other officers. Subordinate to them are eight inspectors of the provinces, who make regular tours through the districts assigned them, to examine the various factories, and give in a report of them to the chamber. In cases of importance, such as the advance of funds, the nomination of commissaries and factors, granting new privileges, erecting new manufactures, the interdiction of foreign commodities, the raising or lowering customs and imposts, &c. The chamber of commerce can de-

erec nothing without first consulting the board at Vienna, and receiving its directions. The exchequer of commerce has considerable revenues, and, in case of being exhausted, is supplied by that of Vienna. The interior commerce of Bohemia is much facilitated by the excellence of the roads. Ten grand roads issue from Prague, and run through the whole country in an invariable line. In many places they are supported by mason work; and there are deep ditches on both sides, to facilitate the flow of the waters. These roads were completed at the expense of several millions of florins, though the tenantry were obliged to give their labour without hire. Two creutzers, equivalent to about 1s. 11d. are paid at every stage, for defraying the expense of making and repairing them. The Empress and Queen Maria Theresa, established, in 1749, a regular mail to run from Vienna to Prague, and another from Prague to Vienna, both to favour commerce, by the facility of intercourse between the two capitals, and to furnish travellers with proper accommodation.

The name Bohemia is derived from the German *Bochman*, which signifies *the residence of the Boii*. The Boii were a branch of the Celts, who, under the command of Sigovesus, passed over from Gaul into Germany, about 600 years before the Christian æra. Proceeding as far as the frontiers of the Quadi and Sarmatians, they settled in that part of the Hercynian forest which then covered Bohemia. In the reign of Augustus they were invaded by the Marcomanni, who expelled them, and took possession of their territory. Some of the conquered nation, however, still cantoned in Bohemia, though the greater part of them took refuge in Noricum, the modern Bavaria. The Marcomanni remained in possession of Bohemia till the 6th century, when they were, in their turn, attacked and dispossessed by the Slavonians, under the command of Czechow. This leader governed with such clemency and moderation, that his name is still cherished with reverence by the Bohemians, who take particular pride in the appellation of Czechs, or Czechowians. In those countries, indeed, where the Slavonian language is spoken, they are known by no other name. Czechow found the country almost in a state of nature, covered with wood, and occupied by herds of wild cattle, which no owner could claim. He taught the savage inhabitants to cultivate the ground, and to rear crops of corn, and thus rendered them acquainted with some of the comforts of life, and prepared them for the restrictions and the advantages of regular government. We have no means of ascertaining what particular form of government was established by Czechow, or what title he assumed; but the title of duke was first adopted in Bohemia by Premislaus, who flourished about the commencement of the eighth century. Premislaus is said to have founded the city of Prague, and to have distributed his subjects into different ranks: the government was transmitted to his descendants; one of whom, named Borzivori, embraced the Christian religion about the close of the ninth century, and found means, not without some violent struggles, to establish it throughout his dominions. Upon the death of his son Wratislaus, his widow, Drahomira, an inveterate enemy to the Christians, massacred about 300 of them in one night, burnt their temples, and compelled them to surrender their arms. Her son, Wenceslaus II. was a zealous friend of the Christians, but had not reigned many years when he was murdered by his brother, Boleslaus I. surnamed the Cruel, who persecuted the Christians

with unrelenting rigour, and forced them to abandon the kingdom. They were again protected and cherished by his son, Boleslaus II. surnamed the Pious, who founded and endowed a number of churches, and obtained leave from Pope John IX. to create a bishop at Prague. An insurrection of his subjects, occasioned by their dislike to some reforms which he attempted to introduce, was quelled by the Christians, aided by the Jews, who, in return for this service, were allowed to build a synagogue in the capital. The ducal form of government continued till the year 1086, when Wratislaus II. was invested with the dignity of king by the Emperor Henry IV. who at the same time gave him possession of Lusatia, Moravia, and Silesia. The regal title, however, was at this time confined to Wratislaus himself; and it was not till the close of the twelfth century, or the commencement of the thirteenth, that the sovereigns of Bohemia were permanently honoured with the appellation of kings. From their attachment to the interest of the Emperor Otho, Premislaus II. who began to reign in 1199, and his immediate successors, were styled Othogari. Premislaus Othogar III. who succeeded to the throne in 1255, obtained possession by conquest of Austria, Carinthia, Stiria, and other southern provinces, and, marching into Prussia for the defence of the Christians, defeated his opposers in several engagements, and prevailed on many of the people to embrace the Christian faith. On his return to Bohemia, the imperial crown was tendered to him, but he rejected it with disdain. It was afterwards given to Rodolph, count of Hapsburgh, to whom Premislaus refused to do homage, or to receive from him the investiture of his estates. He was at length compelled, however, to submit, and to deliver five standards to Rodolph, for the five fiefs which he held. A reconciliation took place between these rival monarchs, and Othogar was invested in Bohemia and Moravia, on condition of renouncing Austria, Stiria, and Carinthia. Premislaus was succeeded, in 1278, by Wenceslaus V. who was likewise elected king of Poland, and was offered the sceptre of Hungary, which he refused in favour of his son. In 1310, this dynasty became extinct; and the Bohemian sceptre fell to John, son of the Emperor Henry VII. of the family of Luxembourg, who had married the youngest sister of Wenceslaus VI. John resigned the kingdom of Bohemia to his son Charles, and, having procured for him the imperial dignity, proceeded with him to France to assist Philip against the English. He fell in the battle of Cressy, in 1346. The Emperor Charles IV. created his brother John, Marquis of Moravia; established an university at Prague, upon the plan of that at Paris; and engaged Pope Clement VI. to erect the see of Prague into an archbishopric, assigning to the archbishop the official privilege of crowning the king of Bohemia. This public spirited monarch enlarged his capital by the addition of the new city, in which he founded the college of Carlestein; reduced the laws of the kingdom into a written code, known by the name of the Caroline Constitutions; and projected the junction of the Moldau and the Danube by means of a canal, which was begun before his death, but the completion of which has been found impracticable. He was succeeded by his son Wenceslaus VII. a profligate and tyrannical prince, during whose reign the doctrines of reformation were introduced into Bohemia by John Huss and Jerome of Prague. On the sudden death of Wenceslaus, the Hussites, headed by John Zisca, acquired considerable strength; and when Sigismund, who

succeeded his brother as king of Bohemia and emperor of Germany, advanced from Hungary to take possession of the throne, he was met by their deputies, who entreated that he would allow them to worship God according to their conscience. Their petition was rejected; and a civil war ensued, in which the troops of Sigismund were frequently defeated. At length, after an opposition of sixteen years, he made several important concessions in favour of the Hussites, and was admitted into the capital with great solemnity, and much apparent joy. Sigismund was succeeded, in 1438, by his son-in-law, Albert of Austria, who continued in possession of the crown, though not without considerable opposition, for 33 years, when Vladislaus, already king of Poland, was elected by a majority of the states, and soon after invested by the emperor. His son Lewis, who succeeded him in 1516, had reigned only ten years, when he was defeated by the Turks at Mohatz, and was drowned in the Danube, in endeavouring to make his escape. The sceptres of Bohemia and of Hungary now passed into the hands of Ferdinand, archduke of Austria, and infant of Spain, who had married Anne, the only daughter of Vladislaus. He was afterwards elected emperor, and, at a diet of the states, held in 1547, he declared the kingdom hereditary and absolute. Since that time, both the imperial crown and that of Bohemia have continued in the house of Austria. The immediate successors of Ferdinand made no unwarrantable abuse of their arbitrary power; but the cruel and violent proceedings of Ferdinand II. roused the Bohemians to revolt, and induced the Protestant princes to combine for his destruction. The crown was torn from his head, and presented to the elector palatine. A civil war continued for 30 years to distract Bohemia, and so dreadful were its horrors, that more than 30,000 families are said to have taken refuge at this time in foreign countries. Some idea may be formed of the desolations occasioned by this revolution, from this striking fact, that, in the reign of Rodolphus, scarcely two centuries ago, the population of Bohemia amounted to three millions of souls, whereas, after the civil wars, it did not exceed four hundred thousand. After the peace of Westphalia, Ferdinand III. and his successors remained in tranquil possession of the throne of Bohemia, till the death of Charles VI. in 1740, when the elector of Bavaria preferred his claim to the sovereignty of that country. This claim gave rise to a new war, and Bohemia was again ravaged by fire and sword. Peace was restored in 1745, since which time, the right of the house of Austria to the Bohemian crown has never been disputed. As a prince of the empire, the king of Bohemia is the first secular elector, and does homage to the emperor for his states. In every other respect he acts as an independent sovereign, nor is there any appeal from the decrees of his tribunals to the tribunals of the emperor. He is hereditary archbutler of the holy Roman empire, and from this office derives a right of voting for the king of the Romans. Bohemia, though a genuine state of the Roman empire, was exempted by Ferdinand II. from contributing to its taxes, and rendered independent of the jurisdiction of the supreme judicatory of the empire. At an act of the diet, called the Admission, held in 1708, it was acknowledged by the three colleges of the empire, that the king of Bohemia has an unquestionable right to sit and vote in all its assemblies; and, at the same time, the emperor came under an engagement to pay for his hereditary kingdom of Bavaria, and the countries belonging to it, his electoral

proportion of all taxes and imposts to the empire and circle, besides 300 florins annually to the chamber judicatory. The states of the empire resolved, at the same time, to take the kingdom of Bohemia under their protection.

Bohemia was formerly divided into sixteen departments; but a new division was adopted by the states assembled in diet in 1714, according to which it was distributed into twelve circles, Haurzimer, Pilsner, Leutmeritzer, Konigingratzen, Rakowitzen, Chrudiner, Pra-chiner, Staner, Bunzlauer, Saatzer, Czaslawer, and Bechiner. To these circles must be added the territory of Eger, which is not included in any of them. This division was approved of by Charles VI., who ratified it by a particular decree.

The government of Bohemia is entrusted to six courts, viz. the council of the regency, or great royal council, which is composed of the great judge, or burgrave of Bohemia, with eighteen lieutenants of the king, and other assessors; the council, or superior chamber of justice, in which the grand master of the kingdom presides; the chamber of fiefs; the new tribunal, for judging the appeals of the German vassals, having a president, vice-president, and other assessors; the royal chamber of finances, having a president, and vice-president; and the chancery, which always follows the court. The states consist of the clergy, nobility, and deputies from several towns, who meet annually at Prague, rather to receive the orders of the court than to enact any decrees of their own.

The Bohemians are in general handsome, active, and strong. Dubravius, bishop of Olmutz, who wrote in the 16th century, thus describes his countrymen in the fanciful language of that age. "As this land is under the influence of the lion, so its inhabitants have the qualities of that noble animal. Their high breast, their sparkling eyes, their long and thick hair, their vigorous limbs, their strength, their courage, their resistance to obstacles, every circumstance shews evidently that the lion is their star, as he is their emblem." They are without comparison the best of the imperial troops. None of those troops can bear up, as the Bohemians do, under the fatigues of war. The state of poverty in which their peasantry live, gives them habits of temperance, which at once invigorate their constitution, and render them incredibly patient of hunger, to every German soldier more formidable than death; and the system of feudal servitude which here prevails in all its rigour, accustoms them from their infancy to unlimited obedience, the first of military virtues.—No middle rank is known in Bohemia; for there every man is either a petty sovereign or a slave. Of late, indeed, the peasantry on the imperial demesnes have been released from the bonds of feudal slavery, and it is to be hoped that the benevolent example of the emperor will be generally followed by the Bohemian nobility. Till that time, it is in vain to expect any improvement in science or the arts; for a land of freedom is their only congenial soil.—Bohemia can boast, indeed, of several public seminaries; an university, twelve gymnasias, 2219 German schools, 200 schools of industry, and 33 ladies' schools. Yet learning is almost wholly neglected; though the success of those few who have applied to study prove that this neglect is owing rather to the circumstances of the country, than to any want of genius in its inhabitants. They are uncommonly fond of music; and the orchestras of Prague are said to excel even

those of Paris in exactness of harmony, and brilliancy of execution. In general they are addicted to travelling; and when in foreign countries, live in the greatest amity, and repose in one another unbounded confidence.

Bohemia contains 250 cities, the principal of which is Prague; 308 borough towns; 11,455 villages; and 430,000 houses. The following official Table, published in 1786, will give an idea of the proportion which exists in Bohemia between the different kinds of rural economy:

	Sq. Acres.	Sq. Fathoms.
Arable land	3,609,360	776
Fish ponds	67,115	1373
Fields	220,136	1593
Meadows	978,393	1066
Gardens	85,712	722
Ponds used as meadows	65,515	970
Pastures and heath	613,131	1209
Vineyards	4,482	672
Woods	2,219,811	575
Total	7,783,660	8738

Its contributions to the empire, according to the manual of Frankfort in 1803, amounted to 15,735,000 florins; according to HOCK, 15,500,000; according to OCHART, (1803) 16,500,000 florins. Population 3,022,000.

The established religion of the country is Popery; but by the humane and judicious regulations of Joseph II. both Protestants and Jews are allowed the free exercise of their worship. BOHUS, or BAHUS, a province of Sweden, bounded on the north by Norway, on the west by the Schaggerack, and on the south and east by West Gotland. It extends about 100 miles from north to south, and about 20 from east to west. The country is productive, and watered by rivers and lakes, which produce plenty of fish. Wood, fish, pitch, tallow, hides, and lime, are its principal articles for exportation.

This province takes its name from a fortified island situated at the southern extremity of the province, and encircled by two branches of the Gotha. The fortress, which is built on a rock, was erected in 1309. Its situation is strong, and it is garrisoned by 100 men. (j)

BOILEAU, NICOLAS, (Sieur Despreaux), one of the most able poets whom France has produced. He lived during the reign of Louis XIV. and rose to a high distinction in the cluster of wits, whose coexistence has ranked that period among the golden ages of literature. He was born in 1636; and his various works were successively offered to the public, between 1666 and 1707. He sprung, according to his own information, from a race of lawyers (*Fils d'un pere Greffier, né d'aucun Avocats*;) and was the youngest of three brothers, all of whom were ambitious of writing for the public. The

oldest, an advocate, produced a life of Epictetus, and a translation of his philosophy from the abridged view of it supplied by Arrian. He also composed occasional verses, of which a collection was published after his death. Jacques, the second brother, was Dean of the Faculty of Divinity in Paris, and a voluminous author on ecclesiastical subjects. We shall mention the titles of two of his works, for the amusement of those, whose more rational faith will tempt them to smile at the trifles, to which the dignitaries of the Gallic church attached a serious importance. One treatise of the Dean was, *De tactibus impudicis, dans lequel il prouve que ces sortes d'attouchemens sont des pechez mortals*: and another, *De re vestiaria hominis sacri, dans lequel il pretend qu'il est assez indifferens aux Ecclesiastiques de porter des habits trop longs ou trop courts*. Nicolas having finished his academical course at the college of Beauvais, engaged, by the persuasion of his father, in the study of law; a study, to the repulsive inelegance of which, both France and England are indebted for some of their favourite poets. By apprising a youth of the mental exertions most uncongenial to his taste, it leads him, by that species of association resulting from contrariety, to those in which he delights; while a profession less hostile to the play of imagination, might have occupied him sufficiently to prevent the discovery. Boileau, however, proceeded far enough to be called to the bar. On quitting it, he became a student of theology, at the Sorbonne; but was again disgusted, and says that here he found Chicane had only shifted her dress. After this repetition of disappointment, he resolved to indulge his literary propensities, without the interruption even of a literary profession, though he humorously acknowledges that his relations were displeased with the resolution:

La famille en pâlit, et vit en fremissant
 Dans la Poudre du Greffier un poete naissant.
 On vit avec horreur une muse effrenée
 Dormir chez un Greffier la grasse matinée.

To poetry, in which he had both delighted and excelled at Beauvais, he now returned with fresh avidity; and it may be presumed that, even as a poet, he reaped some advantage from his two unsuccessful experiments to alter his destination. They had acquainted him with characters and topics, at which the satirist has frequent occasion to glance, and his acquaintance with which enabled him to sharpen the poignancy, and enrich the humour of his principal production. In France, as in Britain, the public taste was, at this period, extremely vicious, and authors had become popular, by exposing whose faults, and thus obliquely correcting their admirers, Boileau began to prepare the latter for a favourable reception of his own attempts to revive the graceful simplicity of the ancients. In this application of his talents we perceive their early vigour; for to outrun the judgment of our age, to resist the current of fashion, and to reject the support of popular decisions, are the efforts of no ordinary mind, nor is genius less manifest in leading back from error, than in leading forward to truth. The Satires of Boileau, which he wrote with this design, being admired in manuscript, and surreptitiously primed, an accurate edition of them was published by himself in 1666. Their appearance enraged the host of minor poets, who loudly complained of the introduction of their names; but these complaints only served to aggravate their sentence, by provoking Boileau

to a severe and sarcastic apology in his 9th satire. His independence, however, was more conspicuous in the affairs of literature, than in those of life: for Horace was not more profuse of incense to Augustus, than Boileau to Louis, who was then the darling of Fortune, and therefore the idol of subjects, to whose national egotism, success is virtue. To that prince he addressed two epistles, on his different achievements, and also an ode on the surrender of Namur, which shews that its author had misjudged his powers, when he attempted to follow Horace into the higher regions of Parnassus.

Of his *Lutrin*, which he says, in the original preface, was the first attempt of any French writer in *heroic comic* poetry, four cantos were published in 1674, and two more added in 1683. Boileau at first was anxious to conceal the origin of this masterly production. In his preface he misled the reader, by a false account of it; but, in 1683, he threw off the disguise, and acknowledged that the poem was founded on a quarrel between the treasurer and chanter of the Holy Chapel at Paris, about the position of a reading desk. His next publications were, the *Art of Poetry*, and a translation of *Longinus*, with notes, which exhibit much critical penetration and sagacity. These works were not only relished but rewarded by Louis, who bestowed a pension on their author, and appointed him jointly with his intimate friend, the celebrated Racine, to write the history of his reign. To improve their qualifications for this duty, the two royal historiographers visited the army in Flanders, which was then engaged in the siege of Ypres. The duty, however, notwithstanding this pompous preparation, was never executed. It is curious to observe, that the illustration of the military exploits of Marlborough, like those of his royal antagonist, should have been entrusted to two poets (Glover and Mallet), and that in both cases, by an additional coincidence, the reward should have been conferred, and the task neglected. In 1683, Boileau was elected a member of the Academie Française; and, soon after, of the Academie des Inscriptions. To the former of these he published an address of thanks. About this time a violent controversy had arisen in France respecting the comparative merit of the ancient and modern authors, in which Boileau took a zealous part, as an advocate for those classical writers, the successful imitation of whom is among his principal merits. His chief opponent was Perrault, and the controversial ardour of the disputants produced many valuable additions to the maxims of criticism, though it was also the unfortunate cause of much personal animosity. With Fontenelle the quarrel of Boileau never abated, but with Perrault it terminated in a cordial reconciliation, of which the poet, in the triumph of a benevolent nature, hastened to apprise the public. Boileau, we have seen, was a successful courtier; and Louis, who must have possessed a part of that taste which he affected, added to his pecuniary favours the personal distinction of reserving a weekly hour for conversation with the poet. On the death of Racine, however, his friend and colleague withdrew from court, and dividing his time between the country and the capital, slid down the descent of life with more enjoyment than is the usual lot of literary genius. Like Pope, whom he resembled in his moral as well as in his mental character, but unlike the majority of other poets, he was addicted to no dissipation, and so careful to suit his expenses to his means, that he even incurred the imputation of avarice. Pope, by his figure and infirmities, and Boileau, as is supposed, by the effects of an accident,

in an early operation for the stone, were deterred from certain gross pursuits, which have embittered and abridged the days of numbers, to whom mankind are indebted for their most refined gratifications. After enduring, with patient serenity, the frequent intimations of approaching dissolution, in pain, faintings, and fever, Boileau died of water in the chest, on the 11th of March 1711, in his 75th year.

The character of Boileau differed widely from what the circumstances of his life would lead us to expect. In general, when men abandon a profession for the seductions of poetry, this radical irregularity diminishes their dread of others, and involves them in errors, for which the pleasure derived from their genius cannot always purchase our indulgence. The case was otherwise with Boileau, whose conduct was guided by the same good sense and correctness which chiefly recommend his compositions. As he was not among that elevated order of poets, whose loftiness occasionally swells into extravagance, neither did his actions exhibit any of that negligent vehemence, by which the former too often defraud themselves of outward respect and inward repose. He had, by his own information, in his fifth epistle, a sufficient patrimony to warrant the indulgence of his peculiar taste; and though he was certainly too lavish of courtly adulation, with which even his *Lutrin* is artfully interlarded, yet this proceeded more from the contagion of universal practice, than from a profligate or parasitical cupidity. The force of mind, which qualified him to judge for himself, and to oppose the prevailing corruptions in literature, was not sufficient to make him stand alone, in a hopeless effort to separate triumph from applause, or to measure splendid actions by moral rules, which he knew the loyal vanity of Frenchmen would reject. The esteem which he deserved, appears from the number, the cordiality, and the duration of his friendships; and from the encomiums which his worth extorted even from those whose works he had ridiculed. Though his intimacy with Racine was so tender and impassioned, as to make the latter, on his deathbed, rejoice at escaping the misfortune of surviving him, yet such was the benignity of his nature, and such his uniform sympathy with genius, that when Corneille, the rival of his friend, was about to lose his pension, he sued with success to madame Maintenon for its continuance, which he offered to purchase by the resignation of his own. From the charge of avarice he ought to be absolved, by a fact so decisive, as well as by his generosity to Patru, (the chosen censor of his works before publication,) whose library he not only purchased at a price much greater than distress would have compelled its possessor to accept, but also allowed him to retain it for life. In the catalogue of poets, it is a relief to the mind to discover one whose virtues we can thus extol; nor is it among the slenderest merits of his sovereign, that he was studying the comforts of those who had added to his rational pleasures, while Butler and Otway were amusing a prince who permitted them to starve.

As a writer, Boileau was more distinguished by rectitude of judgment, than by richness of imagination. He was, therefore, less qualified to invent, than to improve the inventions of others; and though he could seldom create new materials for poetry, yet of those which were prepared, he could frame a more chaste and beautiful edifice than preceding architects. Though far from deficiency in original thoughts, yet his singular power of giving the gloss of novelty to the ideas of

others, suggested to the Journalists of Trevoux a charge of plagiarism, which roused him, towards the end of his life, to a severe reply, in his epistle "on l'équivocation." Plagiarism was a term by no means applicable to the practice of Boileau, which is most happily described by La Bruyere, when he says, "*Que Despreaux paroissent créer les pensées d'autrui*;" and by Dryden, when he observes of Jonson, "he has done his robberies so openly, that one may see he fears not to be taxed by any law. He invades authors like a monarch; and what would be theft in other poets, is only victory in him." Boileau appears to have looked with comparative indifference on the charms of external nature, and even on human conduct, when modified by lofty passions, or extraordinary situations. Like Pope, he preferred the study of man as he appears in ordinary life, or as he is fashioned by local and accidental habits. His genius, therefore, turned to ethical, didactic, and satirical poetry; and this circumscription of his ambition left him more at liberty to attend to the minuter decorations of his art. His familiarity with ancient authors, which, as it was not conspicuous in his youth, must have been owing to the voluntary preference of his maturer years, when he became *studieux amateur et de Perse et d'Horace*, made him anxious to transfuse the classical graces of regularity and smoothness into the versification of his country. Previous to this period, the French and English poets had been inattentive to rhyme and measure, and trusted more to the value of the cargo, than to the beauty of the vehicle. Here, therefore, Boileau perceived an opportunity for the exertion of his talents; and while the wit of Butler was procuring not only pardon, but applause, for slovenly and harsh expression, Boileau was studying the combination of melody with mirth, and exemplifying the precept, which he couches in the following lines:

N'offrez rien au lecteur que ce qui peut lui plaire;
Ayez pour la cadence une oreille severe—
Le vers le mieux rempli, la plus noble pensée
Ne peut plaire à l'esprit quand l'oreille est blessée.

Though Boileau and Butler agree in the application of mock-heroic irony to the follies of religionists, the characters of their satire differ as widely as comedy from farce, or as the polished eloquence of a legitimate pulpit, from the vigorous and impressive, but endless and unequal harangue of the conventicle. Butler overlays us with an accumulation of wit, and fatigues us with the learning by which he increases its ludicrous effect. Boileau, inferior in both, accommodates them with more address to ordinary readers, and calculates more correctly, from the nature of the mind, the period when attention must flag, and risibility languish from excess. He also verifies the remark of Johnson, that "the learning of the French is, like their food, not the best, but they know how to cook it." In Butler, we are surfeited with substantial, but inelegant, profusion; while Boileau, by the rapidity and lightness of the repast, prevents any decay of appetite till it is finished. Of all the British poets, Pope has been most frequently compared with Boileau. There seems to have been a natural resemblance in their minds; and

Pope was enabled by the priority of Boileau, as Boileau by that of Horace, to transfuse into his writings more of it than might otherwise have appeared. In the works of both we find the same bias to ethical severity; the same abundance of pointed and proverbial couplets; the same felicity in complimentary or reprehensory criticism; the same classical correctness of design; and the same copious mellifluousness of numbers. It must be allowed, however, that Pope possessed a greater variety of talents than Boileau; for we doubt if the latter was capable of producing any thing so pathetic as the "Epistle of Eloisa," or so original as the fanciful machinery of the *Sylphs*; and in lyric poetry Boileau sinks farther beneath Pope, than Pope beneath Dryden. The "Rape of the Lock" and the "Lutrin" have been always considered by critics as poems of the same class, though the latter, perhaps from its subject, appears to shade at times into the coarser manner of the *Dunciad*. The follies of fashionable life admitted of a light and smiling airiness of ridicule, which would not have harmonized with the rebuke of ignorance, gluttony, and sloth. Between the two poems, however, there is an obvious likeness, from parity of conception and felicity of execution; from the wit which sparkles in the parts, and the seasoning of humour which enriches the whole.* In humour we, indeed, consider them as nearly equal; but on comparing their wit, we apprehend the balance will incline to our countryman. Our limits not permitting the enlargement of these remarks, we shall close them with the literary character of Boileau, which was drawn by Voltaire with his usual discrimination. *Incapable peut-être du sublime qui élève l'ame, et du sentiment qui l'attendrit, mais fait pour éclairer ceux à qui la nature accorda l'un et l'autre, laborieux, severe, précis, pur, harmonieux, il devint, enfin, le poete de la raison.* (w)

BOILING. See CHEMISTRY.

BOIS, DU, or Lake of the Woods, a lake in North America, situated to the north-west of Lake Superior, and to the south of Winnipeg lake. This lake, which is nearly round, has a cluster of islands in the middle of it, so large, that by those who sail past them, they have been taken for the main land. Large quantities of oak, pine, fir, spruce, &c. grow upon its banks, and from this circumstance it derives its name. It stretches about 70 miles from east to west; and, in some parts, it is about 40 miles wide. See Mackenzie's *Voyage from Montreal through the Continent of North America*, *Introd.* p. 59. (j)

BOIS-LE-DUC, SILVA DUCIS, or the DUKE'S WOOD, called also *Hertogenbosch*, which has the same meaning, is the capital of Dutch Brabant, and is situated at the confluence of the Dommel and the Aa, in a low, sandy, but cultivated tract, almost surrounded by a morass. This city was built in 1184, by Godfrey III., duke of Brabant, who had been accustomed to resort to that quarter for the pleasures of the chase. The town is of a triangular form, and above three miles in circumference. It has four gates, one towards Breda, called Vucherpoorte; another towards Grave and Nimeguen, called Hintemppoorte; a third towards Bommel and

* Between wit and humour we take the distinction of Mr Jackson, whose precise words, however, we do not recollect. Wit he represents as a sort of intellectual legerdemain, by which we are led to expect one idea, and surprised by the dexterous substitution of another, as a juggler leads us to expect an egg, and discovers an orange. A juggler is a wit in things; a wit is a juggler in ideas, and a punster in words. Humour again, without these sudden changes, produces its effect by pretending a disposition contrary to what the subject naturally creates, as by censuring with praise, and praising with censure, or by treating a light subject gravely, and a grave subject lightly.

Utrecht, called Orterpoorte; and a fourth towards Heusden, called St John's Gate. It is defended by a castle, called Papen Briel; by the fort of Crevecoeur, near the Meuse; the large fort of Isabella; and a small fort towards Brabant, called St Antoine. The town is regularly fortified, and its walls are flanked by seven bastions. The approaches to it by land are on causeways, and by water at three gates, called the Grand Heckel, the Petit Heckel, and the Boom. The cathedral, built in 1366, is one of the finest edifices in the Low Countries. Its wooden tower, which was so lofty as to be seen all the way from Antwerp, was supported by four stone pillars, but was destroyed by lightning in 1584. There were formerly other four churches, but three of them are now used as warehouses. When this town belonged to the Catholics, it contained 16 monasteries. The monastery of the Jesuits is now the governor's palace. There is likewise in this city a college, and a town hall which is an exact miniature of that of Amsterdam. There are here 51 stone bridges, and 3 made of wood. The adjacent country can be easily laid under water, and sometimes in winter the town can be approached only in boats. The principal manufactures of Bois-le-Duc are, linen cloths, needles, knives, and several articles of iron manufacture. Population 9600. East Long. $4^{\circ} 59'$, North Lat. $51^{\circ} 40'$. (q)

BOKHARA. See **BUCHARIA.**

BOLABOLA, or **BORABORA**, one of the Society Isles, in the Southern Pacific Ocean, discovered by Captain Cook in July 1769. It is about seven leagues in circumference, and is surrounded with a reef, nearly full of productive and populous islets. As its shores are rough and precipitous, it has only one harbour. A lofty double peaked mountain rises in the centre of the island. This mountain is barren on the east side, but has bushes and trees on its craggy parts. The lower grounds towards the sea are covered with cocoa, palms, and bread fruit trees. It is said that the first inhabitants of Bolabola were malefactors banished from the neighbouring isles, that the fame of their military talents increased with their numbers, and that they gradually extended their conquests over the other islands. West Long. $151^{\circ} 52'$, North Lat. $16^{\circ} 32' 30''$. See *Missionary Voyage*, Introd. p. 41. (j)

BOLCA, **MOUNT.** About eighteen or twenty miles north-east of the city of Verona, there is a small village called Bolca, from which a mount, or hill, receives the same appellation. The village itself is not of sufficient consequence to merit a particular description, but it is otherwise with the hill, for in its substance are contained some of the most remarkable natural productions which the world affords.

Around Mount Bolca, and throughout the territory of Verona, unequivocal volcanic remains demonstrate the prevalence of subterraneous eruptions, and also that the whole must have once been covered by the sea. Numerous petrifications of plants, shells, and marine animals, are dispersed in the earth, but frequently in such an arrangement, that beds in one district are confined to certain species unmixed with others, while the same peculiarity is observed in districts more remote. In the mountains, whereof Bolca is one, there have been found 27 genera of Testacea, hitherto unknown; and not less than 200 species of petrified shells have been dug from the tufa, marbles, and basalts, of which the neighbouring territory is composed. By a wonderful accumulation, shells, whose animals inhabited different

seas and different climates, are collected together in the same heap, along with those which never retreat to water. There are also many petrifications of zoophytes, consisting of the articulations of asteriæ, clusters of corals and madrepores; and in this unaccountable aggregate, the parts of terrestrial quadrupeds, of birds, and of insects, are not wanting. The bones of huge elephants, stags, and bears, and likewise those of an intermediate tribe, the phocæ, have been discovered. Basaltic columns of various kinds are seen on Mount Bolca and in the neighbourhood, differing not only in structure, but in the proportions of their elementary parts. Their figure is hexagonal, pentagonal, quadrangular, and even triangular; and their position is generally perpendicular to the horizon; but at San Giovanni d'Ilarione they exhibit a degree of obliquity, as if some disturbing cause had altered their position. Burnt earth, scorix, lava, and other volcanic productions, are scattered about the Purga di Bolca; and the hill itself, barren of vegetation, is covered with earth intermixed with animal and vegetable remains. These circumstances, added to the natural phenomena which will come under our consideration, plainly shew, that the tract environing Mount Bolca has been subject to volcanic eruptions, and that the sea has covered it at some very remote period. At present, the nearest shore is fully fifty miles distant from its base.

Part of what passes by the general name of Mount Bolca, is situated at a short distance from the real hill, and called Lastrara; so that, according to the strictest topography, they should be separated: but no such division being spoken of when those who precede us treat of the productions of the place, we shall follow their example, in considering Bolca and Lastrara as synonymous.

All the fossils of the Veronese territory are inconsiderable when compared with innumerable petrified fishes found in Bolca, where it would seem as if the whole seas and rivers of the globe had concurred in depositing their contents. Those of Europe, Asia, Africa, and America, areuddled together in one confused heap: the fishes of the torrid zone are mixed with those of temperate climates; those of fresh water rivers with those of the most extensive seas, and all differing in habits, structure, and properties. Large masses of stone, detached and unconnected with the ordinary substance of Mount Bolca, lie imbedded in the side of the hill, 1000 feet above the level of the sea. Quarries penetrating into these, have exposed the fossil fish to view. The stone containing them is calcareous, of a schistous structure, and susceptible of being split into flags; or laminæ, of various thickness and dimensions; and it has been denominated by mineralogists a marl or marley schist. It is of a whitish, yellowish colour, or of a bluish grey, and some of it is quite black. Its hardness, though of different degrees, is such as commonly to yield to the knife, but not to the nail; and it has one characteristic peculiarity, which consists in emitting a peculiar fetid odour on being struck or rubbed, compared to that of swine-stone. This odour, the Abbé Fortis, in treating of petrified shells found not far from Bolca, supposes to proceed from animal putrefaction. On splitting the flags asunder, the remains of petrified fishes appear of a dark brown colour, and are consequently very conspicuous on the light ground of the stone. They lie flat between the laminæ; their contour and component parts being little, if at all, distorted from

their natural shape and dimensions; but sometimes there is an enlargement or defect, arising either from the changes undergone in passing from an animal to a fossil state, or by the stone apparently having been affected by motion after they were inclosed within it. Their whole form is completely defined, and the harder parts, such as the head, fins, spine, and other bones, are still more evident. The dark brown substance composing the fish remains quite distinct, and projects from the laminae of the stone, in proportion to the size of each part in its natural state, and it may be separated from the stone. It is hard, brittle, and rather glossy, excepting some of the larger bones, such as the joints of the vertebræ, which, though presenting the same external appearance, exhibit cavities filled with beautiful crystals. The different colour of the slate, or flag, inclosing the fishes, has been ascribed by naturalists to the chemical effects of their bodies on the stone, which is not improbable, on reflecting that it could not be originally in an indurated state. Fossil fish are found in various parts of the world, and high above the present level of the sea, but no where in the same abundance as in the quarries of Mount Bolca; and the fishes of this hill are further distinguished from the impressions usually seen in argillaceous schistus, as well as from the petrifications of shells found in limestone strata. In the latter nothing more than the simple impression of the fish remains, and the external shape of the shell is alone preserved, whereas, in the productions of Bolca, the form and size of the animals are not only admirably exhibited, but there even seems to be the residue of animal matter in that substance, which we have said may be detached from the stone. Inspection determines it to be of a different nature from that of the inclosing stone, and, so far as could be judged without analysis, those naturalists who have bestowed most attention on the subject, conclude it to be animal remains; and that it is in a condition similar to the flesh of mummies; from which circumstance Volta denominates the state of these fishes *natural embalming*.

Most of the fishes of Bolca are such as now inhabit the European seas, but there are some species peculiar to the rivers of India and America exclusively, while there are many belonging to the fresh water streams of our own and neighbouring countries. It is asserted by observers, that petrified American fishes are found in no other part of Europe, notwithstanding there are numerous impressions of European ones in France, Switzerland, Germany, Britain, and elsewhere.

Of many hundred specimens dug from the quarries of Bolca, the species amount to 94; the rarity or abundance of which is extremely diversified, as well as the size of each. Some have been found three feet in length; and, in 1789, the *fugasus natans*, a small fish, was dug out of Lastrara, which, from its minuteness, almost escaped notice. Thus the natural agent affecting their transition from the animal to the fossil state, has equally operated on the bodies of all. A young shark, now preserved in a cabinet, merits particular observation. It is only 25 inches in length, wanting a small portion of the tail, and four in breadth; and more perfect than any of the same genus found in Bolca, though the remains of sharks of much larger size have been procured. The ravenous nature of the animal is disclosed by the contents of its stomach, which exhibits a quantity of sea crabs; but it is wonderful to remark, that these are in a half digested state. Considering the voracity of such fishes,

it is evident that death must very soon have followed the capture of the prey. Certain appearances denote incipient putrefaction, which plainly proves, that the commencement of the transition to the fossil state must have speedily arrested its progress. The sudden change which ensued is further corroborated by the skeleton of two fishes imprinted on the same stone; one of which has seized the head of the other, and seems in the act of swallowing it. This is esteemed one of the most singular productions afforded by Bolca. The genus *chatodon* has more frequently been described than others, either from readily occurring, or from being better adapted for preservation. Scheuchzer long ago observed, that the *chatodon fimmatus*, a fish commonly inhabiting the Arabian and Indian seas, was dug out of Bolca; and more modern European naturalists, on comparing the fossil with the real animal, ascertain, that, in the transition undergone, some parts have either enlarged or become defective. The *chatodon mesoleucus*, lately transmitted from Japan, and which still lives in the seas of Africa also, is found entire in Bolca. This fish, which is neither mentioned by Artedi nor Linnæus in its living state, was first discovered by Förskhal on the shores of Arabia; and Bloch afterwards received it from the island of Japan. Gmelin, however, in his edition of the *Systema Naturæ*, probably being influenced by the remoteness of these two regions from each other, has formed two species which seem to constitute only one. The fossil extracted from the quarries of Bolca corresponds with both. Among the finest specimens procured, is the *chatodon argus*, bearing a minute and perfect resemblance to that caught in the rivers of India, or in stagnant lakes, where it feeds on insects, and animal substances supplied to it. The *chatodon argus* is conjectured to pass through extensive seas, for it has been described as inhabiting places many degrees asunder. So far as hitherto ascertained, the *chatodon arcuatus* has never been seen in the European seas, yet it is dug out of Bolca. Maregrave enumerates it among the fishes of Brazil, and Artedi classes it with those inhabiting India. Two specimens from the hill, which are still preserved, first proved it to have anciently existed in Europe. There is a fish of uncommon structure, called the *sea bat* by the older ichthyologists, and thence *chatodon vesperilio* by the moderns, which very few have described. Willoughby speaks of it, but it was unknown to Linnæus, and seems to be found solely in the seas surrounding the island of Japan. One individual, of small size, has come under the inspection of a celebrated naturalist; but another, considerably larger, though in a fossil state, has been taken from the excavations of Bolca. The latter is ten inches in length, from head to tail, and nineteen and a half in extreme breadth: Several of the pectoral and ventral fins are defective, but their origin is still quite conspicuous. Two other specimens of the same fish are likewise extant. A species of ray, which is scarce to be recognised in the European seas, was found in the immediate vicinity of Bolca, along with three univalve fossil shells imbedded in the same stone. It is twenty-three inches long, and nine broad, and exactly resembles a new species inhabiting Arabia, called *raja sephen*; some are discovered three or four times as large. The fishes of Mount Bolca are by no means confined to genera and species now extant; for various specimens have appeared hitherto undescribed, and which are still unknown. The *uranoscopus rastrum*, so named in its fossil state, has never been seen

as a living animal; and the most careful comparisons of all the specimens found, remove it from any analogous species. We shall dwell no longer on this division of the natural products of Bolca; catalogues of which have been published in Italy, shewing what species belong to the seas of the four quarters of the globe, and what are exotic fresh water fishes. Besides these, several rare species of fossil crabs are obtained from the quarries, such as the *longimanus*, *setifer*, and *locusta*, of which the specimens are particularly fine. Among the insect tribes, there have been dug up an *omiscus*, *cæstrus*, two *asili*, and an American *cimex*. Complete exuvie of marine serpents are sometimes, though rarely, laid open; and numbers of marine plants are imprinted on the stones. The parts of birds are less frequent in a fossil state than those of any animals; but a petrified quill was once found in Bolca, and lately preserved at Verona, as an exception from the general rules of nature in accomplishing this extraordinary transition.

A profound and interesting problem arises on the formation of this singular hill, and the substances which it contains. First, How can such an aggregate of animals, inhabiting regions so many geographical degrees asunder, have been collected in so limited a space? Secondly, How are the fishes inhabiting salt and fresh waters respectively, which may almost be denominated different elements, intermixed? And, thirdly, How have the bodies of such soft and destructible animals been able to resist the usual decomposition of nature, undergo a transition to stone, and remain entire from a period of such remote antiquity? Various theories may be offered on these questions, which, in this place, we shall not pretend to discuss, as they will partly come under our consideration in other articles. But there are some points which peculiarly relate to Mount Bolca itself, on which we shall make a few observations.

It is evident that the sea has once overflowed the highest mountains. Beds of shells, and strata of calcareous substances, added to the impression of fishes on stone, besides many other concurring circumstances, prove the truth of this assertion. It is clear, therefore, that the Veronese territory, which presents all these indications in the most conspicuous manner, may have anciently been submerged, or even may have been the bottom of the sea. In various portions of the globe the waters have receded; and we know, that, in certain places, their gradual retreat has been slowly exhibited in successive ages. At the same time, it is not improbable that they may here have at once been withdrawn by some violent convulsion of the earth; a fact which has been exemplified in the course of the preceding centuries. But supposing that they naturally covered the Veronese territory, it is far from easy to account for the diversity of fishes belonging to remote climates being found in the same spot, especially as the heat of the torrid zone seems indispensable to their existence. Yet, without recurring to the gradual refrigeration of the earth, or the gradual change of climate in limited districts, which we are well assured has followed, two circumstances ought to be preserved in view: Nothing can be more imperfect than our acquaintance with the finny tribes. Genera and species innumerable have never met the eye of mankind; and it is justly remarked by a modern ichthyologist, that our principal knowledge of their distinguishing characters have first been derived from those served up at our repasts. Can we affirm with confidence, that any fish of the Mediterranean is

unknown in the Pacific Ocean, or that many in the Greenland Seas do not frequent the shores of Britain? Skillful naturalists are aware, that animals are daily discovered in one region, that have been referred to and described as peculiar to another; and that, with care and attention, even when removed from their original liberty, they may be preserved and propagated in climates not naturally their own. Neither can we overlook an important fact, relative to the temperature of the elements, which terrestrial and aquatic animals respectively inhabit. The air is subject to constant vicissitudes from external causes, but it is probable that the temperature of a vast body of water always continues at nearly the same degree; nay, it is probable, that, with the exception of extreme cases, the temperature of the sea, above fifty fathoms deep, is not very different all over the world. Hence it is possible, supposing the genera of Mount Bolca and those of the Indian Seas to be identified beyond dispute, that both may have enjoyed a requisite degree of temperature when a deep sea covered the territory of Verona. Fishes, however, are more privileged than terrestrial animals, in the facilities of seeking a temperature agreeable to themselves; if the surface of their element undergoes refrigeration, they have only to plunge farther into its depths; and the body being too immense to be susceptible of sudden vicissitudes, they have time to withdraw from one parallel of latitude to another, as their sensations may require. We know, that certain fishes can support a considerable change of climate without injury; and that some, transported north from places far to the southward, have been naturalized. Thus, we cannot with absolute confidence maintain, that the fishes hitherto thought peculiar to the warmer climates could not live in the seas covering Mount Bolca, or that they did not enjoy that degree of temperature which was necessary to their nature. Perhaps those seas may have been heated by the effects of the volcanoes, whose remains are scattered over the territory; for although great bodies of water cannot be suddenly affected by a change of temperature, the shallows immediately surrounding volcanic mountains and isles have been known to melt the pitch of vessels sailing close by their sides. Such shallows are always a grateful abode to fishes: there they flock together in numbers, and perhaps find more copious supplies of food in the marine insects which the heat conspires to propagate and diffuse. The atmosphere is likewise greatly heated by the fires of constant volcanoes; and it has been affirmed, that one of the most productive islands in the globe is rendered so, principally by the constant flames of eight volcanoes. In this way, the temperature of the Veronese territory may have anciently been augmented. It is infinitely more abstruse attempting to explain how salt and fresh water fishes are intermixed; for although it be very possible, that, by gradual and almost imperceptible transitions, they might be reciprocally brought to live in either; or successive generations, by passing from greater or lesser degrees of saltiness or freshness while in the ovular state, might habituate the perfect animal to the change; as we have not witnessed the fact, we cannot maintain that it has taken place. Still it is to be remembered, that some fishes dwell in salt or fresh water indiscriminately; that we do not know whether confinement to one of them only is destructive; and that there is a minute resemblance between the species of the same genera which inhabit both.

The presence of the sea, however, on the Veronese territory, is not indispensable to the existence of the fishes of Bolca. A volcano on the surface of the earth may have been the sole agent. Some philosophers affirm, that all volcanoes have a communication with the sea by subterraneous caverns. Mount Vesuvius vomited quantities of water in 1538, and in later times: and *Ætna*, in 1755, cast up salt water, mixed with stones and sand. But we have still more decisive proof, how essential volcanic agency might be in producing the fishes of Bolca, from learning that vast quantities of a species of small fishes have been discharged from the burning craters of mountains in South America; sometimes in such extraordinary numbers, that their putrefying bodies threatened to create a pestilence in the land. Volcanic eruptions in the vicinity of the sea, or of lakes, are commonly fatal to vast multitudes of fishes; on which account, those which issued from the Peruvian mountains might have perished before being absorbed by the craters. Pliny, in describing the fatal catastrophe wherein his uncle perished, remarks, that the sea suddenly ebbed during the eruptions of Vesuvius, and many animals remained dry on the sand: and centuries afterwards, a similar phenomenon allowed the inhabitants of the neighbourhood to collect the fishes lying dead on the shore. During the rise of new islands from the sea of the Greek Archipelago, dead fishes continued to be thrown up during a whole month on the sand: and an instance, still more noted, was seen in 1742, at the port of Vera Cruz in Mexico. A sudden agitation of the sea on the 19th of October, threw down part of the wall of the city, and threatened the vessels in the harbour with destruction. Next day incredible quantities of fishes covered the beach, lying in heaps on each other; and consisting of many species altogether unknown to the fishermen: nor were they confined to the vicinity of the port, as the same appeared at the distance of leagues from it. The heaps were so great, that, to avert the danger of putrefaction infecting the atmosphere, all the slaves of the place, and the crews of the royal gallees, were employed in burying them in the places where they lay. The like phenomenon was renewed in the island of Sumatra, in the year 1755, when an amazing multitude and variety of fishes, some dead, others dying, were found on the shore. We are, therefore, entitled to maintain, that fishes may be vomited from the crater of a volcano; and to conclude that volcanic eruptions are sometimes singularly destructive of those in the surrounding seas. Different theories are entertained respecting the cause of their death. Some naturalists conceive that a mephitic vapour is suddenly diffused throughout the water, which immediately becomes fatal to the animals within its sphere; that they are involved in showers of volcanic ashes, which then become the deposit of their bodies, and the source, as in the case before us, of their future preservation. The fishes of Bolca have unquestionably perished by sudden death, as is demonstrated by the half digested food in the stomachs of some of the most voracious. Those who oppose the deposit being formed at the bottom of the sea, maintain, that the fishes, once exposed on a dry shore, might easily be covered and invested by showers of ashes, which, while forming a crust around them, would aid the absorption and evaporation of the water; and that their gradual accession is particularly favourable to preserving the figure of the animals enclosed, from the superincumbent weight not being sufficient to

crush them. As the strata of Bolca, along with fishes, contain the leaves of trees, terrestrial plants, fruits, and flowers, and even some winged animals, this hill could not be at the bottom of the sea when the deposit was formed, because the lightness of leaves always buoys them up on the water. Volcanic showers also are heavy enough to break them off the trees, and are even capable of killing birds; and that peculiar odour emitted by the flags is improperly referred to an animal principle, for it should rather be called bitumenous. The ashes discharged in forming the new islands of the Archipelago were mixed with much bitumen, which served as a gluten to bind them together, consolidate them, and involve the substances which they covered. Those from an eruption of Vesuvius in 1737, spread over the gulf of Venice, and at Zannichelli diffused a similar odour, which assuredly, say the partizans of this doctrine, could not be imparted by putrefying fishes. "Volcanic showers," in the words of Domenico Testa, "having fallen on Bolca, destroyed and burned together, the fishes of the sea, the birds of the air, the trees, and plants of the earth. Thus did an eruption form that celebrated cemetery of fishes, which for two centuries has equally been the admiration of the learned, and the wonder of the ignorant. It might be the work of a few hours, or at most of a few days; a truth which should so much the more impress those naturalists who, on the phenomena exhibited by the fossils of Verona, form self-convincing arguments for the prodigious antiquity of the world."

Several reasons are advanced by Testa on the possibility of the rise of Mount Bolca not being of very ancient date; but these perhaps were suggested by his anxiety to make the antiquity of the world exactly correspond with the common, though perhaps erroneous, interpretation of scripture; and in countries like his, so lately under the papal dominion, if it was dangerous to think the reverse, it was still more so to express it. "How many facts in natural history," he exclaims, "have happened in ages not remote from those in which we live, but which have passed unnoticed and unremembered! The celebrated Lago d' Agnano, near Naples, did not exist towards the middle of the 9th century; but when was it afterwards formed? In what part of the territory of Pozzuolo were those gold and silver mines situated, from which the bishops levied a tithe in 1135? Under the reign of what prince were they abandoned? The Venetian chronicle of Sagornino, which is not more ancient than the 11th century, speaks of certain islands in the Lagoon of Venice, which no longer exist. In what year did they disappear? In the 15th century, part of Giera was inundated by the sea; but we know nothing of its total desiccation. Neither can we tell when the city of Gabi, lately discovered in the Campagna di Roma, whose succession of bishops terminates in the 8th century, ceased to be inhabited; for it is disclosed in no history." He therefore concludes, that although we may also search history in vain for the precise epoch when the sea washed the foot of Mount Bolca, and when the volcanoes of Lombardy still vomited flames, we are not altogether void of traditions respecting it. Four thousand years ago, the sea may have extended to the Vicentine mountains, and may have formed so many islands of Berici and of the Euganean hills. The names of extinct volcanoes being in the Italian language, induces Testa to suppose that their craters have remained open subsequent to the Christian æra; for he cannot ascribe to simple chance those, such as *Montenuovo*.

Monterosso, Monterugio, Moncenere, and the like. He cites examples of volcanic eruptions in the Vivarais, proved to have existed in the 5th century, by the prayers offered up for their cessation. They have long since been extinct; though it is unknown when they ceased to burn. "Mount Bolca is scattered over with lava; basaltic prisms crown its summit; and even the quarries containing its fishes are covered with a deep stratum of volcanic tufa."

Theories not dissimilar from that of Testa are entertained by other philosophers; for all who have studied the phenomena of this hill, incline to refer them, in a great measure, to volcanic agency; at the same time judging the presence of the sea indispensable. They maintain a principle, which we are inclined to support, that the fishes extracted from the excavations of Bolca could be only a short time dead before they were enclosed in the substance surrounding them; and as a necessary condition, that this substance must have been in a very fine and pulverised state, and either suspended in the water, where the fishes swam, or subsiding from it. Thus, the water containing them would be clear and fit for supporting life, and the diffusion of the pulverised matter must have been suddenly effected, whereby it arrested and enclosed the fish in the masses formed by its deposit. Certainly the deposit, excluding the access of water, was speedily effected, otherwise the progress of putrefaction, so powerfully promoted by humidity, would have injured the figure of the animals, and the various gases disengaged, would have deranged the laminar structure of the flags it formed, by their fracture or the formation of cavities. All this, the advocates of the theory we allude to, explain by supposing, that the explosion of a submarine volcano, suddenly discharged a vast quantity of calcareous matter into the sea above it. The fish within its sphere were destroyed, the matter became pulverised, and subsiding to the bottom, enclosed them in the deposit. "The stone (where the fishes are enclosed) is wholly calcareous, of a light colour, of a grain dull, though fine, and entirely devoid of any crystalline or sparry appearance. Now, it is well known, that limestone, whatever its original colour may have been, becomes uniformly white or whitish, on being calcined or burnt, more or less, to a lime; that after this calcination, it immediately slacks or falls into a powder, on being immersed in water; and by agitation is easily diffused in this element, from which, if left in tranquillity, it soon subsides in a pulverulent state. That this diffusion of lime in water, quickly deprives of life such fish as happen to be within its reach; and, in fine, there is every reason to believe, that a deposition of this nature possesses remarkably the quality of quickly absorbing, even in water, oily and other soft parts of animals; and when sufficiently slacked, and thus impregnated with animal matter, without destroying the harder and firmer parts." Applying this theory to the appearance of the flags dug out of Bolca, it is supposed to receive a strong confirmation from their structure. The deposition of the lime gradually and successively concreting at the bottom of the water, it is said, "may naturally be expected to assume a flag like or laminar structure; the grain, too, of this new aggregate, should be wholly without lustre, as well on account of its calcination as of its formation, by subsidence from, not in consequence of solution in, a liquid menstruum; in which last case alone crystals are known to be formed. This will farther easily account for the formation of the calcareous spar found within the prominences occasioned

by the joints of the vertebræ, and the other grosse bones; for these being fresh and sound at the first arrangement of the stone, of course excluded the subsiding matter; but in process of time, their hollows were filled, and by degrees as it decayed, their substance was replaced by a successive filtration of water, holding calcareous matter in solution, which deposited plate after plate its crystalline matter in these cavities." The fetid odour escaping by friction on every part of the stone, is considered a strong presumption also, that its whole substance has absorbed a great proportion of animal matter.

Admitting the truth of the general principle, on which these theories are founded, there are still many difficulties to be surmounted, and one of the most important lies in the structure of Bolca. This hill is not a homogeneous mass; it consists of various substances, in unequal proportion, and forming four classes, according to geologists, among which are marl, spar, basalt; coal and amber; pyrites and hæmatites; marine plants, insects, fishes, and the remains of terrestrial animals in a state of petrification. The petrified substances do not lie in horizontal strata; horizontal so far as would result from the deposit of pulverised matter on an uneven surface; for the masses of stone wherein they are contained are imbedded in the sides of the hill: they seem detached and apart from the other parts composing it, and rest in various degrees of inclination. But perhaps this may be accounted for, by supposing, that subsequent to their formation, they were exposed to some violent disturbing cause, which affected their original position. There is no necessity that such disturbing cause should have approached the æra of their formation; on the contrary, appearances indicate that it has existed at a time very remote from it. If the fishes were suddenly destroyed by some pernicious vapour, absorbed by the water where they swam, or by some lethal quality otherwise imparted to it, they must have remained for ages in their original state. The open mouth and distended fins exhibited by them, naturalists have conjectured denote immediate suffocation; after which they were involved by the component matter of the stones containing them, and themselves converted to stone. But that the deposit was made on a surface at rest, is evinced by the laminar structure of all the strata; their whole leaves are parallel to each other, and perfectly flat; where their continuity is interrupted, the extremities are sharp and cleanly cut off, as if by fracture in their horizontal position. Though the time requisite for complete petrification is unknown, we may presume that it is slowly accomplished; and if we are to credit the correctness of an observation, that in 1500 years wood was not affected above a quarter of an inch in depth, the period must almost exceed the bounds of calculation. Therefore it is not unlikely that two great epochs are to be counted in the formation of Mount Bolca and its singular fossils: first, that which occasioned the sudden destruction of an infinity of living beings, and their undisturbed envelopment and investiture at the bottom of the sea, by the substance diffused; and secondly, the disturbance of that deposit from its original level, which may probably have been accomplished by some violent convulsion of the earth. But the one may have followed the other at an immense interval of time. Had it happened soon after the animals in question perished, their tender and corruptible substance would have soon been so essentially altered, as to preclude all possibility of recognising them at the

present day. Surely we need not anticipate objections from the force required to implant the huge calcareous masses in the sides of Bolca. If rocks are projected from burning craters, mountains raised, or islands formed in unfathomable seas, what power is there which violent convulsions of the earth are unable to overcome?

The curiosities afforded by Bolca, had, centuries ago, attracted the notice of ingenious and speculative minds: and thence the peasantry and labourers of the neighbourhood have gained a livelihood by procuring them. Blocks of moderate size are detached from the face of the quarries; and being brought out and set on edge, are split asunder with sharp hammers or wedges. The workmen then examine the leaves, to discover whether there be organic remains of fishes or other substances; and should they discover any such, which are generally shattered from the rudeness of the operation, they collect them with the greatest care: the pieces also that adhere to the stone, are cautiously separated from it. When their daily occupation is completed, the workmen carry the collections they have made to their own houses, where they are kept until delivered to their employers in Verona. The pieces are taken thither in baskets, and either given to the owner of the soil, or privately sold to dealers in such productions, or to naturalists desirous of acquiring them. It is said that the purchaser, who obtains the fossils in this state from the workmen, is then obliged to employ a skilful lapidary to search out and arrange the pieces composing each specimen, and cement them on another stone of the same kind. So much art and accuracy are sometimes used in doing this, that it is scarcely possible to discover the places of junction; and it is thus that the specimens are prepared for sale, or for cabinets. As a greater or less proportion of the brown matter of the bones, fins, and other parts of fishes, sometimes adhere to one side in splitting the stone, and sometimes to another, or is frequently divided between both, the more valuable specimens consist of duplicates; for when the pieces are well and skilfully put together, their prominences correspond with the cavities in the opposite half. Most of the specimens hitherto extracted have come from one principal quarry in the side of the hill, called *Pescaia* by the inhabitants of that territory; but there are several besides, supposed to be of later discovery, all equally abounding in petrifications. The people, however, who attempted to form excavations being poor, and no funds being specially appropriated for this curious research, which would have been attended with considerable expense, nothing important followed. The soil where the quarries lie, has belonged to different owners, who were solicitous to obtain its contents.

The variety and singularity of the fossils discovered on the surface and in the recesses of this hill, afford so much scope for philosophical contemplation, that unusual care has been taken to collect and preserve them. Extensive cabinets, from which all other varieties were excluded, have thence been formed of them alone; and these have passed into the hands of successive owners, along with a right to explore the soil, in the same manner as we are wont to transfer the richest territorial property. The first cabinet of the productions of Bolca with which we are acquainted, was collected by a person distinguished in the pharmaceutical art, Francesco Calceolari, who flourished in the sixteenth century. He is celebrated by Aldrovandus, Gesner, and other

cotemporary authors, for his knowledge of natural history; and left a work on the contents of his cabinet, *Descrizione de Museo Calceolari*, which was published after his decease by *Andrea Chiocco*. Nearly a century later, Count Ludovico Moscardi, having the same propensities for study, formed a cabinet, partly consisting of the petrifications of Bolca. Still more recently, a member of the noble family of Rotari and Count Andrea Gazola, were occupied with similar pursuits towards the earlier part of the 18th century. The former, who died in 1744, addressed a learned epistle to Vallisneri, on the subject of the fishes of Bolca; and the latter laid the foundation of the most celebrated of all collections of this description, which still subsists in his nephew's possession. Soon afterwards, the learned Marquis Scipio Maffei, equally distinguished by his skill in polite and antiquarian literature, as in exploring natural phenomena, purchased the quarries. Assisted by M. Seguier, a French botanist, he was long engaged in recovering the fossil remains of animals, numerous specimens of which were dispersed among the naturalists of Europe. Nearly about the same time, Giacomo Spada, a priest of Grezzana, which is a place situated among the Veronese mountains, following in the footsteps of Maffei, soon formed a respectable collection, which constantly increased during his life. When he died, in 1750, it passed into the hands of Maffei, from whom M. Seguier acquired it; and by him it was carried to the city of Nismes in France, where it yet remains. Spada published three different works on the petrifications and fishes of the territory of Verona. The loss of his museum, and of the collections of Maffei to that country, were partly indemnified by Julius Cæsar Moreni, whose cabinet was enriched with numerous petrifications, but particularly fishes. The whole was on his death acquired by the Marquis Ottavio di Canossa. Near to the period when the labours of Moreni ceased, those of the most celebrated of all the collectors, Vincenzo Bozza, a learned apothecary of Verona, commenced. Twenty years were occupied in forming his museum, which neither expence nor trouble were spared in rendering complete. He purchased the soil wherein the quarries of Bolca lie, or obtained permission from the heirs of Maffei to renew the excavations; and, towards the year 1770, began to found a collection, from its owner denominated *Gabinetto Bozziano*, which was famed over all Europe. The activity of Bozza was not less excited by his love of investigating the profound phenomena which his researches tended to elucidate, than by the desire of surpassing those cotemporaries who were engaged in the like pursuits. At length his cabinet contained 700 specimens of petrified fishes, besides many other animal and vegetable substances, recovered in the same state from the territory of Verona. Amidst such a number of specimens, 69 different species of fishes could be distinctly identified, setting aside others whose characteristics were not sufficiently prominent to give them an appropriate place in the arrangement. "In my cabinet," says Bozza, "which contains above 600 fishes of different sizes, all extracted from Bolca, there are more than 100 whose kinds are known, which differ from each other in genera and species; and many others besides to which similar ones have not yet been discovered alive." Juan Andres, a Spanish traveller, relates, that Bozza assured him, that he possessed eight species of fishes such as now inhabit the Pacific Ocean, and above 30 other species totally unknown; and he saw

some specimens 30 or 40 inches in length. But the Physical Society of Verona, on stricter scrutiny, have reduced the species to 69. In the year 1794, this magnificent collection was purchased, at a high price, by the Count Giambattista Gazola, nephew to Count Andrea, mentioned above. The Count had himself with great industry procured fossil fishes during the space of eight years, and his museum contained many specimens not to be found in that of Bozza. He likewise acquired the museum of another collector, the Marquis Giacopo Donisi; so that he came into possession of the most splendid and extensive collections which any naturalist had ever enjoyed. From Mount Bolca alone he had above 800 specimens of petrified fishes, many of extraordinary size, and of the finest quality; and the same place afforded him numerous petrifications of crabs, winged insects, and marine plants, of which he was enabled to form a perfect series. See *Societas Physicorum Veronensium, Ittiolitologia Veronese del Museo Bozziano*, 1796. Bozza *Lettera al P. Orazio Rota, sulla universale rivoluzione sofferta dal globo terracqueo*. BOLE. See ORYCTOGNOSY.

BOLETUS, a genus of plants of the class Cryptogamia, and order Fungi. See BOTANY. (w)

BOLINGBROKE, LORD. See ST JOHN.

BOLCHERETSKOI, a town of Kamtschatka, situated in a swampy plain on the banks of the Bolchaia-reka, a river which rises about the middle of the peninsula, and after running northerly about thirty miles falls into the sea of Ochotsk. The town is placed on an island formed by the arms of this river, which divide the town into three parts. The town consists of several rows of low buildings, thatched and built with logs. Each of these buildings consists of five or six dwellings, connected together with a long common passage, which separates the storehouse and kitchen from the dwelling apartments. The principal buildings are a church, a court room, and barracks for the cossacks and Russian soldiers. The river is about six or eight feet deep, and a quarter of a mile broad below the town. The Russian government once proposed to make this place the depot of their commerce; but the harbour affords no shel-

ter from the winds, and as the navigation of the river is extremely dangerous, this idea was abandoned. Population 600. E. Long. 137°, N. Lat. 55°. (H)

BOLOGNA, BOLOGNA, BONONIA, or FELSINA, a city of Italy, formerly the capital of the duchy of Bologna, but now the chief place of the department of Reno, is situated in a beautiful plain at the foot of the Apennines, on the rivers Savona and Reno, the former of which washes its walls, while the latter runs in several branches through the city, and communicates with the Po by means of a canal.

"The ancient name of this city," says Keysler, "was Felsina, from Felsinus, a Tuscan king, who is supposed to have built it twenty-five years before the foundation of Rome." The name of Bononia is by some derived from a successor of Felsina, called Bonus, but others derive it from the Boii."

Bologna, which is of an oblong form, is surrounded with a lofty brick wall, and is about five or six Italian miles in circuit.† The streets are narrow, and rather gloomy, from the fronts of the houses being built upon arcades, and the houses are tolerably built. The pillars of these arcades or porticos, are irregular in different houses, some of them being high, others low, some square, and some round, and some of stone, while others are of wood. The streets where the carriages pass are considerably lower than the porticos, like the rows at Chester. The houses are flat roofed, with a parapet towards the streets, and are covered with tiles.

The public buildings of this city are large and elegant, and are equally remarkable for the beauty of their architecture and for their internal decorations. Next to Rome, Bologna contained the most valuable paintings by the first Italian masters; but many of these noble relics have been carried off by the French to adorn their capital; and while we think that we are noticing the curiosities of Bologna, we may unknowingly be describing the statues and pictures of Paris.

The tower of Asinelli, built by Gerardo Asinelli in 1109, stands in the centre of the city. It is 371 feet high, and is the loftiest in Italy, excepting the cupola of St Peter's. The tower, which is square, is ascended by 464 wooden steps, and inclines from the perpendicular about three feet and a half.

Near this tower is the leaning tower of Garisenda, which is 144 feet high, and inclines about eight feet two inches from a vertical line. It was formerly of a much greater height; but the foundation of it having given way, a great part of it fell or was taken down.

One of the finest buildings of Bologna is the Palazzo Publico, in which the vice legate, the gonfaloniere, and other officers of state had their apartments, and in which the courts of justice were held. It stands in the great market place, presenting a front of 218 common paces. A brass statue of Pope Gregory XIII. executed by Minganti, and weighing 11,300 pounds, stands over the entrance; and at the left of the entrance is another statue of Pope Boniface VIII. On the front of the

* The name *Felsina* has been derived from a word in the language of the ancient Gauls, which signifies a hill, and is supposed to have been given to Bologna, from its situation on the western declivity of the Apennines. "Les Gaulois qui occupaient déjà la vaste plaine qui borde le Po des deux cotes, appelerent le lieu ou elle est située *Felsina*. qui dans leur langue, comme dans la Teutonique, signifiait collé ou petite montagne." *Tableau Historique, Statistique et moral de la Haute Italie*, par Ch. Denina, sec. 16. p. 289. Par. 1805.

† "Bologna is formed in the similitude of a ship, more long than broad, at one side shewing the figure of a prow, and at the other, that of a poop, having in the midst the most high tower Asinelli, which represents the main mast, the lower Garisenda the sails, and the other small towers, the shrouds, to the eye of the beholder." *Italy in its Original Glory, Ruin, and Revival*, by Edmund Warcupp, Esq. Lond. 1660.

palace are two inscriptions, one commemorating the interview between Charles V. and Clement VII. in 1529. and the other the dreadful pestilence which visited the city in 1650. One of the apartments shewn to strangers, is the Salone D'Ercole, which contains a noble statue of Hercules, of a huge size, executed in *terra cotta* by Lombardi. In another little saloon are represented the principal achievements of the Bolognese, inscribed with Latin verses. Above the Salone D'Ercole is the Sala Farnese, which derives its name from a marble statue of Pope Paul III. who belonged to the Farnese family. At the expense of the Cardinal Farnese, the walls and ceiling of this apartment were painted by the best masters of Bologna. The principal paintings are, Francis I. king of France, touching for the evil at Bologna before Pope Leo X.;—the public entry of Paul III. into Bologna;—the aqueduct of Cardinal Alborno; and the coronation of Charles V. The museum of Aldrovandi is also in this palace, consisting of 187 folios, and above 200 bags full of single leaves, written by the hand of that learned naturalist. The cabinet of valuable medals, belonging to the Marquis Cospi, has been added to this collection. The arsenal, containing military stores and artillery, with 6000 stand of arms, are likewise kept in the palace.

Before the palace is an area 370 feet long, and 300 broad, containing a noble marble fountain, which, with the leaden pipes, &c. is said to have cost, 70,000 golden crowns. On the top is a statue of Neptune, eleven feet high, supporting a trident. A number of dolphins ejecting water, and four sea nymphs, with streams issuing from each breast, are placed within the basin. The brass statues were executed by Giovanni di Bologna, the rest by Antonio Lupi, and the whole arranged by Lauretti.

In the private palaces at Bologna are many interesting paintings, which our limits will only permit us to enumerate.

In the palace of Bonfiglioli are several beautiful pieces by the Caraccis, and nearly fifty drawings by the first masters, among which are the massacre of the innocents, by Raphael; Veturia and Coriolanus, by Bap-tista Franco.

The palace of Campeggi, built of freestone, was once the residence of Charles V. In the gardens is a lion of white marble, which was formerly erected at Ravenna by the Venetians.

The palace of Caprara is particularly interesting to travellers. Among the curiosities which it contains are the brass statue of general Caprara, on a pedestal of red porphyry, supported by a Turk. At the corners of a splendid gallery are closets filled with shells and other marine productions; and the other parts of it contain numerous curiosities, and pieces of antiquity, which it would be tedious to enumerate. Among some fine paintings contained in the gallery, is the death of Bragadini, who was flayed by the Turks, painted on wood.

The palace of Favi is enriched with the works of the Caraccis. On the ceiling of a saloon, the adventures of Jason are painted in fresco, in eighteen pieces, by the two Caraccis, under the inspection of their uncle Luigi. In another apartment, twelve paintings from the *Æneid*, are executed in fresco, on the frieze, by Luigi Caracci, from which five etchings have been made by Mitelli. The other adventures of Eneas are painted in ten pieces by Albani; and the other disciples of Luigi Caracci have finished the remainder in another apartment.

The palace of Magnani is celebrated by the history of Romulus, painted in fresco by the three Caraccis. The beauty of the colouring is faded.

The palace of Molari contains a number of pieces by Albani and the Caraccis; a gallery painted by young Cignani; the raising of the siege of Turin, by Antonio Casa; and a much admired painting, representing a woman asleep, while a laughing wanton boy is letting down upon her breast a mouse suspended by a thread.

The palace of Pepoli contains several fine paintings on the ceilings. There is here also a silver triumphal car holding two ladies, which moves round the room by clock work, as if it were drawn by two lions.

The splendid palace of Ranucci is adorned with some beautiful tapestry made at the Gobelins; by a painting of Jerome, and another of Joseph flying from Potiphar's wife, by Guido; and the fall of Haman, by Antonio Gionima, in which the figure of Esther has met with great admiration.

The palace of Sampieri possesses several paintings by the Caraccis, and the *chef-d'œuvre* of Albani, which represents Cupid kissing Venus, and pointing with a triumphant air to the rape of Proserpine by Pluto. There is also here a masterpiece of Guido, called the "Repentance of St Peter."

Besides the palaces which we have enumerated, those of Legnani, Marescotta, and Volta, are worthy of being visited.

The churches of Bologna are both numerous and splendid. They are said to amount to 200, most of which contained some of the finest productions of Italy.

Over the great altar in St Anthony's church is an excellent piece by Luigi Caracci, representing the preaching of the primitive hermits. In the Oratory near this church, is the annunciation by Tiarini, which has been greatly admired.

St Bartholomew's church contains an annunciation, the nativity, and the flight into Egypt, by Albani. The three aisles were painted gratuitously by Angelo Michael Colonna, from a motive of devotion. A fine marble statue of St Petronius, by Brunelli, stands before the church.

In the vestry of the church of the capuchins, is a charming crucifixion by Guido Rheni.

The church *ad Corpus Domini* is adorned with a Christ descending into the *limbus patrum*, and the interment of the Virgin Mary, both by Luigi Caracci.

The Cathedral, or *Il Duomo*, which is a modern structure, is elegantly finished both within and without. It contains a great number of monuments, and is peculiarly rich in marble decorations. On the ceiling of the chapter room is a fine painting by Luigi Caracci, representing St Peter on his knees before the Virgin Mary, and in the tribune of the cathedral is the annunciation of the angel Gabriel, the last effort of the genius of the same inimitable artist.

The church of the Dominicans contains, in a magnificent chapel, the monument of St Dominico, who died in 1221, which is of white marble, and adorned with beautiful basso relievos by Michael Angelo. The vestry contains a great quantity of jewels, along with the Old Testament, said to be written by Ezra. Montfaucon, in his *Diarium Italicum*, says, that this MS. is very ancient, and was presented by the Jews at the beginning of the 14th century.

The chapel of Rosario contains the remains of Luigi Caracci; and possesses such a quantity of plate, that it is

guarded in the night by several mastiffs, and a centinel well armed.

The Franciscan church is enriched with some highly finished paintings by Luigi Caracci, Facini, Brizio, Guido, and Tiarni.

The church called *Chiesa del Buono Gesu*, is of an oval figure, and is ornamented with paintings in fresco by *Pianori*. It contains also a fine statue of our Saviour by *Brunelli*, a marble one of St Apollonia, and one of St Bernardine in terra cotta, both by *Lombardi*. The basso relievo of the circumcision by *Brunelli* is above all praise.

The church of St George, contains the nativity of Christ in fresco, by *Cignani*; the annunciation, by Luigi Caracci; the Virgin Mary, by Annibal Caracci; and the baptism of Christ, by *Albani*.

The church of St Giovanni Battista de Celestini has a high altar piece, containing a picture of the Virgin with the infant Jesus, which they pretend to say is painted by St Luke.

The church of Giovanni in Monte is in possession of an admirable picture of St Cecilia by Raphael. Entranced with the harmony of a choir of angels, the saint dashes all her musical instruments upon the ground. Though the count Malvasia censures the stiffness of this piece, it is highly praised by Addison, and is reckoned one of Raphael's master-pieces.

In the church of St Gregory is a fine piece by Luigi Caracci, representing St George relieving St Margaret from the dragon; a picture of St Gregory performing a miracle, by Dionysius Calvert; a baptism of Christ, by Annibal Caracci; and a large picture of St William, by Guercino.

The largest church in Bologna is the church of St Petronius, famous for being the place where Charles V. was crowned in 1530. It is 360 feet long, and 154 feet broad. The pictures of the clergy in hell, of an executioner beheading a saint with a long sword, and of the coronation of Charles V., are deserving of notice. The principal curiosity in this church, however, is the meridian line, drawn by Dominique Cassini in 1653, and renewed in 1695. The line is half the length of the church, and is equal to the 6000th part of the circumference of the globe. It consists of pieces of red and white marble inlaid, about three or four inches broad, and the pieces on which the signs of the zodiac are cut are a foot square. The marbles, which were quite out of repair, were renewed, in 1776, under the direction of M. Zanotti. The gnomon is 83 feet high; a circular image of the sun, about eight inches diameter, being admitted through a round aperture in the roof.

The church of St Salvatore is adorned with many fine paintings by Luigi Caracci, (the assumption of the Virgin Mary, and the picture of our Saviour, are by this artist,) Girolami Carpi, Guido, Benevenuto Tisio, Samachino, and Cavedoni. The perspective pieces, by Mitelli; the marble statue of Christ, by Brunelli; a MS. of the book of Esther; a Hebrew MS. of the Old Testament; and about 300 other MSS. are among the curiosities contained in this church. The building itself is very fine, having three noble chapels on each side.

The university of Bologna is said to have been founded in 433, by the emperor Theodosius; while others are of opinion, that it owed its origin to Charles the Great. If this monarch had not the merit of being its founder, it was at least greatly indebted to his generosity, and to that of the emperor Lothario. The first pro-

fessor of civil law was Ireneri or Irnerio, who was brought here by Lothario. In the time of Andrea and Azzo, the one professor of canon and the other of civil law, it is said that there were no fewer than 10,000 students at the university. The public college, or university, called *Il Studio*, is 213 common paces long, and was built by Barocci of Vignola. Under the word ACADEMY, we have already given a full account of the Institute of Bologna. In this establishment, the principal objects deserving of notice are the astronomical school, containing a model of the Copernican system, the meridian line, cut through a wall a foot thick, under the direction of Manfredi; the observatory; the college library; the school for experimental philosophy; the academy of sculpture; the academy for painting; the anatomical theatre; and the museum, which contains a large collection of antiquities and natural curiosities. These admirable institutions, of which a full account will be found in Keysler's *Travels*, are owing to the liberality of count Marsigli, one of the generals of pope Clement XI.; who, being dismissed from the service, went to Bologna to spend his fortune in the patronage of the sciences.

Bologna has given birth to a great number of eminent men, who have distinguished themselves in the various departments of literature and science. Azzo, Odofredus, Campeggi, Paleotti, and Ireneri, were among its distinguished lawyers. Mondini Achillini and Marcello Malpighi, were among its anatomists and physicians. Natural history was under obligations to Aldrovandi and Ferdinand Marsigli; and Peter Crescenzi was the first of the modern Italians who wrote a considerable work on the art of agriculture. The mathematicians and natural philosophers were Ghedini, Manfredi, Zanotti, Beccari, Canterzani, Monti, and Galvani.

A very considerable trade in damasks, sattins, taffeties, silks, and velvets, has been carried on in this city since the year 1341. The silk mills are driven by the river Rheno, which also gives motion to a great quantity of machinery for various other purposes. The crapes and gauzes of Bologna are also in high estimation; the works of the gold beaters is much admired; and its manufactures of paper and playing cards were reckoned very superior. The crapes, gauzes, and cards of Bologna were exported to France and Germany, and its hemp and flax went to Venice, for the manufacture of sails and cordage. Artificial flowers of all kinds are made in great abundance by the nuns; and a great trade is carried on in hams, dried tongues, sausages, macaroni, olives, perfumes, wash-balls, liqueurs, essences, and leather bottles.

The surrounding country is rich and fertile, and the neighbourhood of Bologna resembles an immense garden. The vineyards are divided by rows of elms and mulberry trees. The melons, olives, and tobacco are particularly celebrated; and the hemp grows to the remarkable height of twelve and thirteen feet, and has been mistaken by travellers for plantations of young ash trees. The trade of Bologna has been much facilitated by the canal which joins the branch of the Rheno that runs through the city, with the lake of Valle di Marara, from which the merchandise of Bologna is sent to Ferrara, and other places situated on the Po.

In the time of the Roman republic, Bologna was but a small town, with two gates; and it is only mentioned in Greek and Latin authors as deriving its name from the nation of the Boii. It would appear from Martial, (*Epi.*

lix. lib. 1.) that, under the first emperors, the Bolognese were particularly polished; and we are expressly informed by that author, that one of the most lucrative trades in this place was that of a shoemaker. Though inferior to the surrounding cities, Bologna gradually rose in importance. It acquired celebrity from the interview between Octavius, Anthony, and Lepidus, in an island formed by the Rheno, and from several events during the civil war of these triumvirs. It was not, however, till the 12th and 13th centuries, that it became a great and a learned city. It enjoyed a species of independence under the emperors of Germany till the year 1278, when it was given over to pope Nicholas III. with the exception of some special privileges. The internal discord with which it was agitated, and the wars with neighbouring states, kept it in an unsettled condition, till Julian II., taking advantage of the Venetian war, made himself absolute master of it, expelled the family of the Bentivoglio, and annexed it to the papal dominions. It was stipulated, however, that the Bolognese should have a nuncio at the court of Rome, and an auditor in the Rota; that the town should not be overawed by a citadel; and that the effects of the citizens should not be liable to confiscation. The ecclesiastical affairs were decided by the archbishop, while the civil affairs were under the direction of a cardinal legate from Rome, with a vice legate, and other assistants. The police and revenue of the town were managed by a council of fifty senators, whose president was called the *gonfaloniere*, from his carrying the gonfalone, or standard of the republic. Each senator took this office by turns, and continued in it for two months. His authority, however, was merely nominal, as the cardinal legate influenced every decision.

In the year 1796, after this city was taken by the French, Bologna, Ferrara, Modena, and Reggio, entered into a treaty to form a republic under the name of *Repubblica Cispadana*. Some time afterwards, however, these cities united with Lombardy to form the Cisalpine republic. Bologna now belongs to the kingdom of Italy. Population 70,000. East Long. 11° 21' 15", North Lat. 44° 29' 36". See *Italy in its original Glory, Ruin, and Revival*, by E. Warcupp, Lond. 1660. Keyser's *Travels*, vol. iii. p. 247--304. Drummond's *Travels*, letter ii. p. 55. Denina's *Tableau Historique Statistique et Moral de la Haute Italie*, sect. xvi. p. 289. Reichard's *Guide des Voyageur en Europe*, tom. i. p. 439. Marquis Angelette's *Notizie dell' Origine e Progressi dell' Istituto delle Scienze, &c.* 1780. *Travels from Paris through Switzerland and Italy*, in 1801 and 1802, by a Native of Pennsylvania, in Philips' *Collection*, &c. vol. ix. Stolberg's *Travels*, vol. i. p. 265.; and Moore's *View of Society, &c. in Italy*, vol. i. p. 252. (π)

BOLSENA, a town of Italy, in the ecclesiastical state, situated among wooded mountains, on a lake of the same name. The town itself is poor, and is indebted for any reputation it enjoys to a pretended miracle. It is surrounded with a pretty high wall, flanked with towers, and surrounded with a dry ditch.

The ancient Volsinium, formerly one of the chief cities of Etruria, and said to contain 2000 statues in its temples, squares, and streets, stood on an eminence behind Bolsena, where several antique marbles, basso-relievos, &c. are seen among its ruins. Pliny says that it was destroyed by lightning.

The lake of Bolsena, anciently the *Lacus Volsiniensis*, and the *Lacus Tarquiniensis*, is about 39 miles in circumference, and is surrounded with fruitful hills, with several towns and villages at their base. It is frequented by a variety of water birds. Eels of a prodigious size are caught in it; and it contains a great quantity of fish of different kinds. In this lake are two islands, Martana and Bisentina, or Pressentina. The first is very small, and has only a hermitage, with its chapel and a few trees on its margin; while the other is adorned with a fine Franciscan convent, and large gardens. It was here that Amalasontha was assassinated by order of Theodatus. Pliny says that these two islands float about with their groves, sometimes assuming a triangular, and sometimes a globular form.* Between Bolsena and Redicofani are several fine basaltic columns. East Long. 11° 54', North Lat. 42° 37'. See Keyser's *Travels*, vol. ii. p. 89. (o)

BOLSOVER, a town of England in Derbyshire, is delightfully situated on the declivity of a steep hill, which commands an extensive view. The part of the town which is not upon the hill, is surrounded by a very deep ditch and high bank, which extends about half a mile, and is double at the end of the town next the church. There was formerly a castle here of great strength, situated on the summit of a hill, on the north-west side of the town, which belonged to William Peverel, at the time of the Norman conquest. Leland visited its ruins in the reign of Henry VIII. In 1613, sir Charles Cavendish erected, on the scite of the ancient fortress, a modern house, which still exists under the name of the Old Castle. It is a lofty structure, nine stories high, supported by stone pillars, and the most curious Gothic groins. It is partly furnished, and is the property of the duke of Portland. Bolsover was formerly celebrated for its manufactures of bridle bits, stirrup irons, spurs, and buckles; but those articles are now chiefly made at Birmingham. The only manufactory in this place is one of tobacco pipes, which are reckoned the best in England. Number of houses 259. Population 1091, in 1801. (h)

BOLTING MILL. See FLOUR MILL.

BOLTON-LE-MOORS, or **BOLTON IN THE MOOR**, an ancient and large manufacturing town of England, in Lancashire. The town, which is well built, is divided by a rivulet into two parts, called Great and Little Bolton. Even in the time of Leland, this town, and many of the villages in its vicinity, were engaged in the manufacture of cottons and coarse woollen goods. The manufacture of fustians, which is still carried on to a considerable extent, was introduced into Bolton at a very early period. Counterpanes, calicoes, muslins, dimities, and all kinds of articles called Manchester goods, are manufactured here, and are sent to Manchester and Liverpool. Between Bolton and Wigan are found great quantities of cannel coal, of which the turners make snuff boxes, salts, candlesticks, &c. The canal communication with Manchester and Bury has proved of great advantage to the trade of Bolton. The population of Bolton was, in

1773	5,339
1789	11,739
1801	17,416

The number of houses in 1801 was 3386. The num-

* "Insulæ fluctantes---in Tarquiniensi Lacu magno Italiae duæ nemora circumferunt, nunc triquetram figuram edentes, nunc rotundam complexu, ventis impellentibus, quadratum nunquam." Plin. *Hist. Nat.* lib. ii. cap. 95.

ber of males 8177, females 9139; of whom 10,966 were returned as engaged in trade and manufactures. The annual returns of Bolton are said to exceed a million sterling. Lime, veins of lead, and calamine, were wrought in this parish, but not with great success. See Aikin's *Description of the Country round Manchester*, 1795. (g)

BOLTONIA, a genus of plants of the class Syngenesia, and order Polygamia Superflua. See BOTANY. (w)

BOLZANO, **BOLZAC**, or **BOTZEN**, a town of Bavaria, in the Tyrol, situated on the river Eysak, near its confluence with the Adige. It is a fine thriving town, and carries on a considerable business in banking. It has four annual fairs, which are frequented by merchants from Germany and Italy.

The principal foreign merchants who frequent these fairs form a society, which enjoys particular privileges. Those who wish to be enrolled in this association, are proposed by a person of their own religion. They are chosen by ballot, and the votes of two-thirds of those present are necessary for the election of new members. Neither the members of this society, nor their servants, nor their effects, can be arrested within the Austrian States, while going to the fairs or returning from them.

The town was governed by a council, consisting of a deputy, who ought to be a Count, chosen from the higher nobility, three of the order of Knights, and three of the lower nobility, with some burghers and peasants.

In May 1797, Bolzano was taken by the French; but was ceded to Bavaria by the treaty of Presburg. Since June 1808, it has been the capital of the bailliage of Botzen, in the circle of Eisak. This bailliage contains 21½ square miles, and 43,784 inhabitants. (w)

BOMB. See ARTILLERY, GUNNERY, and PROJECTILES.

BOMBAX, a genus of plants, of the class Monadelphia, and order Polyandria. See BOTANY. (w)

BOMBAY, an island on the western coast of India, and the seat of one of the English presidencies. It is situated, according to Mr Howe's observations, in 18° 58' North Lat., and 72° 38' East Long.; and is about seven miles in length, and twenty-one in circumference.

This island was taken possession of by the Portuguese soon after their arrival in India; and was afterwards ceded, in 1662, to the English, as part of the dowry of the Infanta Catharine, on her marriage with Charles II. Accordingly a squadron under the command of lord Marlborough was dispatched to India to receive investiture of the island from the hand of the viceroy; and his lordship arrived at Bombay in September 1663, with sir Abraham Shipman, as governor, on board. The viceroy was disposed to comply with the instructions of his master, but the powerful opposition of the Catholic clergy, who were unwilling that the island should be delivered into the hands of heretics, terrified him into their measures, and determined him to maintain his station. The obstinate refusal of the viceroy obliged lord Marlborough to retire with his fleet to Swally road, for refreshments; and, after having laid in a store of necessary provisions, he set sail, in the beginning of 1664, for England, leaving the rest of the squadron under the command of sir A. Shipman, to spend the remainder of the winter monsoon in some of the nearest ports; and he accordingly remained on the

desolate island of Anjadiya from April to October, during which period he buried upwards of 200 of his men. The monsoon being over, sir Abraham put to sea, and sailed again for Bombay. On his arrival, he threatened the viceroy and the clergy with the vengeance of the kings of England and Portugal, if they continued to refuse obedience to their majesties contract and instructions; and accordingly, they at length agreed to a treaty, by which the inhabitants were to enjoy the free exercise of their religion, and the possession of their estates under the crown of England. But although the trade of Bombay was at this time exceedingly flourishing, yet, as the revenue of the island was not equal to the expense of the establishment, the king, in 1668, made a full grant of it to the East India Company, in whose possession it still remains.

The climate of Bombay is temperate, as, from its insular situation, it enjoys the full advantage of the refreshing breeze, which renders the atmosphere cooler than in many parts of the continent of India. The rains last about four months, and continue with little interruption from about the end of May to the beginning of October. The following Table shews the quantity of rain which fell during this period, in the course of one season:

	Inches.	Tenths.
May,	1	0
June,	44	7
July,	29	9
August,	19	0
September,	11	2
October,	4	5
Total,	110	5

This island was formerly reckoned exceedingly unhealthy, insomuch that it was considered as the grave of the English; but it is now rendered much more salubrious, by the building of a wall to prevent the encroachment of the sea, where it formed a salt marsh; by draining the marshes in its environs; and by an order that the natives should not manure their cocoa nut groves with putrid fish. Nevertheless, many Europeans, especially on their first arrival, are attacked by the diseases common in warm climates; but this, in many cases, is owing to the irregularity of their mode of life.

The soil of Bombay is sterile, and incapable of any material improvement. The vegetable productions of this island are, consequently, very insignificant, consisting chiefly of cocoa nut groves, rice, and some other Indian fruits. However, not a spot of it remains uncultivated; so that although it is far from producing a proportion of food adequate to the consumption of the inhabitants, yet, notwithstanding the disadvantages of its soil and situation, the produce is very considerable.

The city of Bombay is about a mile in length, and is defended, both towards the land and sea, by various fortifications, the construction of which has cost an immense expence. The houses are, in general, neither splendid nor commodious: they are commonly only ground floored; but are not flat roofed, as in the other parts of the East, being covered with tiles in the European fashion. The English have glass windows; but the other inhabitants form their windows of small pieces of transparent shells framed in wood, which renders the apartments exceedingly dark. The floors of the houses

are of a composition of lime made from shells, which, if properly prepared, is extremely durable, and takes so smooth a polish, that a person may see his face in it.

This island is of peculiar importance, on account of its excellent harbour, which is said to be capable of accommodating 1000 vessels at anchor, and is completely sheltered from every wind. On the whole continent of India we do not possess one good harbour; so that, on the approach of the monsoons, all vessels are obliged to stand out to sea, in order to prevent inevitable destruction. At these seasons, the harbour of Bombay, and Trincomallee, in the island of Ceylon, are the only ports we possess which are capable of affording a safe retreat. On account of the peculiar importance of Bombay in this respect, it is furnished with convenient dock yards, and a marine arsenal, for building and refitting ships; and, of late years, a considerable number of vessels have been built on this island, of the celebrated teak wood, which grows on the neighbouring continent; but it is found they can be furnished at a cheaper rate from the port of Rangoon, in the Birman empire.

The population of this island has increased to a singular degree since it fell into the hands of the English. Under the Portuguese government, it is said to have contained only about 10,000 inhabitants; and Niebuhr informs us, that, when he visited Bombay in 1763, they were estimated at 140,000, although within 20 years they did not amount to 70,000, so that in this short period the number appears to have been more than doubled. In the year 1803, Sir James Mackintosh, the eloquent recorder of this island, computed the number of inhabitants at 150,000. These consist of English, Portuguese, Indian Catholics, Hindoos, Persees, Mahometans of different sects, and some Armenian Christians. The English have a handsome church at Bombay; and the establishment of chaplains for their presidency is four in number, but the list is never full. The Roman Catholics have a bishop of Bombay; they are very numerous, and their churches are sumptuously ornamented within. Government does not, however, allow the Catholics to exert their zeal for the conversion of the natives, but under considerable restrictions. If any person chooses to embrace the Catholic faith, the reasons must be laid before the government, and, if they are judged valid, he is allowed to make profession of it. The priests complain of the difficulty of obtaining this permission; but they still meet with considerable success among the negro slaves.

Bombay is the seat of the English government for the coast of Malabar. The council consists of a governor and three members; but they are under the controul of the government-general of Bengal, with respect to treaties of peace with the native powers, the making of war or concluding of peace, collecting and applying revenues, levying and employing forces, &c.; and they are required in all cases to obey the orders of the government-general, unless the directors of the company have sent out contrary orders not known to the government-general, of which, in that case, they are to give the government immediate advice. See Rennel's *Memoir of a Map of Hindostan*, p. 31. Cruttwell's *Gazetteer*, vol. i. Percival's *Account of Ceylon*. Syme's *Embassy to Ava*. BOMBIC ACID. See CHEMISTRY.

BOMBYLIUS, a genus of dipterous insects. See ENTOMOLOGY.

BOMBYX, a genus of lepidopterous insects. See ENTOMOLOGY.

BOMMEL-WAERT, called by Cæsar *INSULA BATAVORUM*, is an island in Holland formed by the Meuse and the Wahal. It is about fifteen miles long from west to east, and nearly six miles broad. It contains the strong town of Bommel, the town of Louvestein, and the three forts of St Andrew, Voorn, and Crevecoeur. The town of Bommel is situated in a plain, fertile in grain and fruits. Its commerce, which was once very considerable, has now passed to *Bois-le-Duc*, chiefly on account of a bank of sand, about 900 feet, which is formed in the Wahal, and prevents vessels from repairing to Bommel. Peuchet says, that the town contains 600 houses, and 300 inhabitants, which is two houses to every inhabitant. He must certainly have meant 3000. (j)

BONA, BONNE, or BLAID-EL-ANEB, the *Aphrodisium* of Ptolemy, a sea port town of Algiers, in the province of Constantia, situated near the mouth of the Scibouse. It was formerly a rich and populous town, but its appearance is now mean, and its population greatly diminished. Although its two harbours are both inconvenient and insecure, from being in a great measure choked up, yet a great quantity of corn, butter, oil, hides, wax, and wool, are annually shipped from the French factory at Bona. The vessels are obliged to lie near the Genoese fort, about a league to the east of the town. The surrounding country produces corn and fruits, and rears great numbers of cattle, but is greatly exposed to the ravages of the wandering Arabs. The town and harbour are capable of great improvement. The Genoese have a coral fishery upon the eastern bank of the bay of Bona. E. Long. 7° 43', N. Lat. 36° 50'. See Shaw's *Travels in Barbary*, p. 46. (j)

BONAIRE, or BUEN-AYRE, the name of one of the windward islands, situated about 60 miles from the north coast of South America. It is about 30 miles from Curaçoa, and nearly 50 miles in circumference. The harbour, which is on the south-west of the island near the middle, is tolerably deep.

Bonaire is inhabited solely by a small number of negroes, and by the Dutch garrison. The former plant maize, yams, and potatoes, and rear goats, which they cure by means of the salt obtained from the salt pond at the south-east extremity of the island. There are horses, hulls, and cows, but no sheep here. The vegetable productions of this island, and the salted goat flesh, and the salt itself, are daily sent off to Curaçoa, as provisions for the garrison and negroes of that islands. Cotton is also produced here. W. Long. 68° 25', N. Lat. 12° 15'. (w)

BONAVISTA, or BUENA-VISTA, the most eastern of the Cape de Verd Islands, discovered in 1450, is about 24 miles long, and 15 miles broad. There are two bays which are frequented by vessels. One of them, called the English Bay, is very spacious, but has numerous shallows. The other, which is called the Portuguese Bay, though less commodious for debarkation, has the advantage of being near the town, and has nothing injurious to shipping but its banks.

The productions of Bonavista are, salt, indigo, and cotton. Those who come here for salt receive it from the mines, and carry it a little distance to a proper place for drying it. The inhabitants then convey it to the ship by

means of asses, which travel in troops of 15 each, every troop being under the charge of a negro.

The indigo, which grows without cultivation, is gathered by the inhabitants; but they have not the art of separating the dye, and of making what in the West Indies is called blue stone. They satisfy themselves with bruising the green leaves in a wooden mortar. They next form it into a kind of paste, of which they make round balls, that are dried for use.

Though the cotton tree grows naturally on the island, yet its culture is greatly neglected by the natives. They never think of collecting it till some vessel arrives to purchase it. Roberts maintains, that the island could furnish annually the cargo of a large vessel; and he informs us, that in some years, when it has failed in the other islands, it has been produced in great abundance in Bonavista.

The surface of the island is low towards the sea, but hilly in the interior, particularly towards the north-east, where there is a hill, probably volcanic, from its resembling a truncated cone. There is still a higher hill in the south-west. The soil is sandy and uncultivated, and the inhabitants live on fish, goats, turtle, and milk. W. Long. 22° 47', N. Lat. 16° 6'. (q)

BOND, in Law, is a deed, or written obligation, whereby a person binds himself, his heirs, executors, and administrators, to pay a certain sum of money, or perform some other act, in favour of another, against a day appointed. A bond in this simple form is called a *single one* (*simplex obligatio*); but, in general, a condition is added, that, if the obligor does some particular act, the obligation shall be void, or, otherwise, it shall remain in full force. If the condition is not performed, the bond becomes forfeited, or absolute at law, and charges the obligor while living; and after his death, the obligation descends upon his heir, who (on defect of personal assets) is bound to discharge it, provided he has real assets by descent.

Executors and administrators are bound, although the words, "heirs, executors, and administrators," should be omitted in the bond; but heirs are not bound, unless they be expressly named. And if a bond be taken to a man, his heirs and successors, the executors and administrators shall have the advantage of it, and not the heir or successor, the bond being in the nature of a *chattel*.

The *condition* of a bond must be such as is *possible*, and *lawful*; and if the matter or thing to be done be impossible, or contrary to some rule of law that is merely positive, or the condition itself be repugnant, insensible, or uncertain, it becomes void, and the obligation stands single and unconditional. If the condition be possible at the time of entering into the bond, but afterwards becomes impossible, by the act of God, the act of the law, or the act of the obligee himself, it is void, and the penalty of the obligation is saved: as if a man be bound to appear next term, and dies before the period arrives. If the condition be to perform any criminal act, or to do any thing that is *malum in se*, as to kill a person, &c. the obligation itself is void. So also are bonds made by *duress*, by *infants*, by *feme covert*, &c. If a bond be made by a *feme covert*, she may plead her coverture, and conclude *non est factum*, &c. her bond being void. But if an infant seal a bond, and be sued thereon, he is not to plead *Non est factum*, but must avoid the deed by special pleading; for his bond is only voidable, and not in itself void.

If no *time* be limited in a bond for payment of the money, it is held to be due presently, and payable on demand. The judges, however, have sometimes appointed a convenient time for payment, having regard to the distance of place, and the time necessary for performance. Where no *place* is specified for performing a condition, the obligor must find out the person of the obligee, if in England, and tender the money, otherwise the bond is forfeited: But when a place is appointed, he is not obliged to seek any further. And where no place is specified for payment of money due on a bond, if the obligor, at or after the day of payment, tenders the money, and the obligee refuses it, the obligor shall be excused; but if he be afterwards sued, he must plead, that he is still ready to pay it, and tender the money in court. If a bond be of 20 years standing, and no demand be proved thereon, nor any good cause of so long forbearance shewn to the court, upon pleading *Solvit ad diem*, it shall be intended paid.

When several persons are bound *severally* in a bond, the obligee may sue all of the obligors, either together or apart; and, in the latter case, he may have several judgments and executions: But if he obtain full satisfaction from one, that shall discharge the rest. When persons are bound *jointly*, and not *severally*, all the obligors must be sued; and if only one be prosecuted, he is not obliged to answer, unless the rest be sued likewise.

When a bond was forfeited, or become single, the whole penalty was formerly recoverable at law: But, in consequence of the interposition of the courts of equity, a man was not permitted to take more than in conscience he ought; that is, his principal, interest, and expenses, if the forfeiture accrued by nonpayment of money borrowed; the damages sustained, upon non-performance of covenants, &c. And it is enacted by the statute 4 and 5 Ann. c. 16. that, in the case of a bond conditioned for the payment of money, the payment or tender of the principal sum due, with interest and costs, shall be a full satisfaction and discharge, even although the bond be forfeited, and a suit commenced. See Blackst. *Comment.* b. ii. c. 20. Jacob's *Law Dict.*

Bonds, according to the law of Scotland, are either *heritable* or *moveable*. The taking of interest being prohibited by the canon law, those persons who wished to make profit of their money, by putting it out to interest, were, before the Reformation, obliged to purchase rights on land constituted by infestment; in consequence of which, the lands were burthened with a certain annual rent to the receiver, redeemable by the proprietor, on repayment of the purchase money. These being bargains affecting land, the rights were understood to be heritable. And even for some time after the Reformation, the form of these rights was preserved, with little variation. But afterwards these rights were changed into proper bonds, by which the debtor becomes personally bound to repay the principal sum, and interest, and, as a further security, obliges himself to infest the creditor in the annual rent. All bonds, therefore, bearing a clause of infestment, are *heritable*.

Bonds merely *personal*, on the other hand, have always been *moveable* before the term of payment; but, afterwards, they were anciently considered as *feoda pecuniæ*, and consequently heritable. But by the statute 1661, c. 32. all sums contained in contracts and obligations are made moveable in regard to succession; although they still continue heritable with respect to the

fisk, and to the rights of husband and wife. The statute excepts bonds bearing an obligation to infest, and bonds payable to heirs and assignees, secluding executors; which continue heritable in all respects.

A bond taken payable to heirs, without any mention of executors, descends, not to the heir in heritage, but to the executor. But a bond taken to heirs-male, or to a series of heirs, is heritable. Bonds, originally moveable, may become heritable, either by destination, or in consequence of a supervening heritable security. But heritable rights do not become moveable by supervening moveable securities.

All bonds, whether merely personal, or even heritable, before seisin, may be affected by creditors, either by the diligence of adjudication, which is peculiar to heritage, or by arrestment, which is peculiar to moveables. Bonds secluding executors, although they descend to the creditor's heir, are payable by the debtor's executors, without relief against the heir. See Erskine's *Prin. of the Law of Scot.* b. ii. t. ii. § 3. *et seq.* (z)

BOND OF BOTTOMRY. See BOTTOMRY.

BONDOU, a kingdom in Africa, situated in W. Long. 11° 50', N. Lat. 13° 53', betwixt the Gambia and Senegal rivers; and bounded on the east, by Bambouk; on the south-east and south, by Tenda, and the Simbani wilderness; on the south-west, by Wooll; on the west, by Foota Torra; and on the north, by Kajaaga. The name of its capital is Fatteconda. The country is woody, and elevated; but in fertility it is believed to be equal to any part of Africa. In the month of December the banks of Falemé, the chief river, are covered with large and beautiful fields of corn, called by the natives *manio*; and by botanical writers, from the depending position of the ear, *holcus cernuus*.

The inhabitants are of the tribe of the Foulahs, of a yellow complexion, with small features, and soft silky hair. They are naturally mild, and gentle in their dispositions; but they consider all the negro natives as their inferiors; and, when speaking of different nations, always rank themselves among the white people.

Their religion is Mahometan, and they pay a sacred regard to the laws and authority of the prophet. Religious persecution is, however, unknown among them; for no molestation is given to those who chuse to retain their ancient superstitions. In the different towns schools are established, in which the Pagan as well as the Mahometan children are taught to read the Koran, on the principles of which, their character and manner are invariably formed. From the nature of their religion, they are less hospitable to strangers, and more reserved in their manners, than their Pagan neighbours. With the Mahometan faith the Arabic language has of course been introduced: their native tongue abounds in liquids, but their articulation is uncouth.

In the occupations of pasturage and agriculture, their industry is remarkable; and it has not only secured to them all the necessaries of life, in the greatest abundance, but also, comparatively speaking, raised them to a high degree of opulence. In the management of their cattle they are extremely skilful, and, by kindness and familiarity, have made them very gentle and tractable.

When night approaches, they collect them from the woods, and secure them in folds; and in the middle of each fold a small hut is erected, in which some herdsmen keep watch during the night, to prevent the cattle from being stolen, and to keep alive the fires which are kindled round the huts, to secure them from the attack of wild beasts. The milk of their cows is of an excellent quality; and is used, but not till it be quite sour, as the chief article of diet. The rich cream affords them great quantities of butter, which, when melted and freed from its impurity, is preserved in earthen pots, for the purpose of seasoning their dishes, and anointing their bodies. They are, however, unacquainted with the art of making cheese; partly from their rooted prejudice against every new invention, and partly from their mistaken belief that the advantage would not sufficiently compensate for a process, which appears to them so tedious and troublesome. They possess also some excellent horses, which appear to be a mixed breed of the Arabian with the original African.

On the river Falemé, whose current is rapid, and its banks rocky, the natives are much employed in fishing; and they catch the large fish in the following manner: They build walls of stone across the stream, open places being left through which the water rushes with great force. Below these openings they place baskets, more than twenty feet in length, made of split cane; and when once the fish have entered them, the force of the stream prevents them from returning. The small fish, which are about the size of sprats, are taken in great numbers in hand nets, which the natives weave of cotton, and use with great dexterity. These are prepared for sale by being pounded entire, the moment they are caught, in a wooden mortar; and then are exposed to dry in the sun in large lumps, like sugar loaves. Their smell is very disagreeable; nevertheless they are esteemed a great luxury, and bring a considerable profit in the Moorish countries, to the north of the Senegal, where fish is little known.

The central situation of Bondou, betwixt the Gambia and Senegal rivers, has rendered it a place of great resort, both for the Slatees, or free black merchants, who trade chiefly in slaves from the coast to the interior; and for occasional traders, who frequently come from the inland countries to purchase salt. They also barter corn for iron, shea-butter,* and gold-dust; and they sell a variety of sweet smelling gums, which are used as perfumes.† The customs and duties on travellers are very heavy. In almost every town, an ass load pays a bar of European merchandize;‡ and in the capital one Indian balt, or a musket, and six bottles of gunpowder, are exacted as the common tribute. In consequence of these duties, the king of Bondou is well supplied with arms and ammunition, and is formidable to the neighbouring states.

The following interesting account of the journey of M. Rubault through the kingdom of Bondou, is given by M. Durand, under whose orders he was employed.

“On the 10th of February 1786, Rubault set off early in the morning, and arrived at noon at the village of Tilliko, a frontier of the kingdom of Bondou: this is probably the same village which Mungo Park calls

* Butter made from the fruit of the shea tree.

† Cotton and indigo are much cultivated: the former they manufacture into a strong cloth, which, when dyed of a deep blue with indigo, they sell to their neighbours the Bamboukians, and receive their gold in exchange.

‡ Bar is the nominal money; a single bar is equal in value to two shillings sterling.

Tallika, and by which he also entered the kingdom. The major part of the inhabitants of this village are Foulahs, who profess the Mahometan religion: they are merchants, who enrich themselves either by supplying the caravans which pass through their country with provisions, or by the sale of ivory, which they procure by hunting elephants, to which they are accustomed from their infancy.

By the 14th Rubault had reached the village of Coursan, the ordinary residence of the king of the country, whose name is Almami. It is worthy of remark, that Mr Park no longer followed the track of my traveller; for he indicates the residence of the king of Bondou to be at the village of Fatteconda, on the right bank of the river Falemé, and at a great distance from Coursan. Both gentlemen saw the king, and have given a description of the palace which he inhabited, which exactly correspond; hence we can only reconcile the difference in the places to arise from the king having palaces at each of them.

His majesty being at a country seat, the stranger was received by his prime minister, who supplied him with provisions, and told him that the king would arrive the next day. On the 14th the queen saw him, and entreated him to stop a little longer, as she had sent an express to her husband, who shortly returned with intelligence that he was coming. An ox was therefore killed; and the king, on arriving, sent for our traveller.

After asking him the usual questions, as to what had brought him into his country, he wished to know, if I had not sent him some present? Rubault answered, that I intended to do so, but that he had distributed all the merchandise which I had given him. He, however, promised to send the king whatever he might wish for, as soon as he arrived at Galam. His majesty appeared surprised, and replied, that his father used to receive great presents from the factory at Galam; but he had had nothing from them. He concluded by adding, that, as Rubault had brought him no present, he would not suffer him to depart. The next day, however, he became more tractable, told him that no harm should happen to him; but insisted on receiving a present, it being an ancient privilege which he would not forego. It was at length agreed, that Rubault should send him a compliment from Galam, which was fixed at two pieces of guinea, a fine musket, four pounds of powder, one hundred flints, one hundred bullets, and a pair of double-barrelled pistols. This demand from so powerful a king was considered as very moderate; nevertheless, by way of making sure of the articles, he ordered three men to go with Rubault as far as Galam, under pretence of escorting him, where they faithfully received the promised allowance, as well as several magnificent presents for the king's women.

The queen having reported her opinion to the other women, they all wished to see the traveller, and he was in consequence conducted to the square where they resided. Immediately on his entrance, they all rushed out, surrounded him, and expressed their astonishment by laughing and shouting. Several of them would touch his eyes, and others, his hands, nose, &c. at which they expressed surprise and curiosity: they then asked him a number of questions, as to the origin of the colour of his skin, as well as about the white women, their amorous propensities, and the conduct of their husbands towards them. Rubault satisfied them as well as he could, and did not fail to flatter them. Indeed, he asserts, that

there were many of them that were handsome and well shaped. Most of them were young: he endeavoured to count them, but could not, as they were continually running about him; he, however, supposes, that there were at least fifty.

The village of Coursan is surrounded with palisades, and contains about 1200 inhabitants. Rubault then continued his journey; and on the 17th quitted the kingdom of Bondou. The duties or customs are very rigorous in this state; and in many of its towns, the value of a bar in European merchandise is paid for the passage of a loaded ass. In the part where the king resides, they demand a musket and a barrel of powder. I lately spoke of the preparations for war, which this sovereign was making against the king of Bambouk: the expedition was successful, and the conquered party was obliged to cede all the countries and villages on the eastern bank of the Falemé.

If it were not for the uncharitable maxims of the Koran, the Foulahs of Bondou, who are naturally good, would be kinder to strangers, and less reserved in their conduct towards the Mandingos: my traveller, however, had nothing to complain of, as he was very well treated.

The government is under the influence of the Mahometan laws, with the exception of the king and his family; but though the great people of the state be Mussulmans, they are wise enough not to sanction religious persecution; and Pagans and Mussulmans consequently live in peace together.

The Foulahs have a particular language; but almost all of them speak Arabic; they are graziers, farmers, and merchants, and every where live in abundance; but at Bondou they enjoy in profusion all the necessaries of life." See Park's *Travels*, chap. iv.; Golberry's *Travels*, vol. i.; Rennel's *Proceedings of the African Institution*; and Durand's *Voyage to Senegal*, chap. xv. (A. F.)

BONES. See ANATOMY, CHEMISTRY, and SURGERY.

BONI, or BONY. See CELEBES.

BONN, the *Ara Ubiorum*, and the *Colonia Julia Bona Verona* of the ancients, was formerly the residence of the electors of Cologne, but it is now a town of France in the department of the Rhine and the Moselle. Bonn is most beautifully situated on the left bank of the Rhine. The streets are narrow and awkwardly built; and, besides perpetually intersecting one another, are dirty and ill paved. The principal objects of curiosity in this place are the metropolitan church, and the fine area before its porch; the town-house, in the Gothic style, which is adorned with paintings; the great rampart, from which there is a charming view upon the Rhine; and the palace, which was formerly the residence of the electors of Cologne. This palace, which stands without the city, was built by the elector Clement Augustus in 1777, on the spot where no fewer than four palaces had been burned to the ground. The prospect which it commands embraces the windings of the Rhine; part of the village of Popplendorf; the *cidruant* monastery of Gruizberg, on the summit of a hill; the spires of Coblenz; and, in the distance, the seven mountains, covered with vineyards. This building is now appropriated for the use of the French government; and in the left wing, towards the Orange Garden, Bonaparte placed the Lycæum, one of the central schools, which is a very flourishing institution, and conducted by able teachers.

Under a quadruple row of lime trees, there is a fashionable promenade, which leads to a small country palace.

About three miles from Bonn are the mineral springs of Draitsch, which contain fixed air, iron, magnesia, and salt. They are situated at the base of the celebrated hill of Godesberg; and an assembly, and other rooms, with pleasure gardens, were constructed on the spot by the late elector, for the comfort of those who frequented the springs. These buildings, however, are now converted into barracks, and about 3500 linden trees, which formed a fine walk to Bonn, have been cut down. Number of houses 1000. Population 8837. East Long 8°, North Lat. 50° 41'. See Carr's *Travels through Holland, &c.*; *An Itinerary from London to Constantinople in 1794*, in Phillips' *Collection, &c.* vol. i.; and Reichard's *Guide des Voyageur en Europe*, tom. ii. p. 241. (w)

BONNER, EDMUND, Bishop of London, was born at Hanley in Worcestershire, and is supposed to have been the natural son of one Savage, a priest; though others affirm, that he was the legitimate son of one Bonner, a poor man, whose residence is still said to retain, in that part of the country, the name of *Bonner's Place*. About the year 1512, he entered a student in Oxford; and, in 1519, he was admitted a bachelor of the canon and of the civil law. He next entered into holy orders; and, by the favour of Cardinal Wolsey, he, at one and the same time, enjoyed the several ecclesiastical livings of Blyndon and Cherry Burton, in Yorkshire; Ripple, in Worcestershire; East Derham, in Norfolk; prebend of St Paul's; and the archdeaconry of Leicester. Being more distinguished by his ability in conducting business than by his learning, Wolsey next appointed him his commissary for the Faculties; and he was with that prelate at Cawood, when he was arrested for high treason. After Wolsey's death, he found means to ingratiate himself with Henry VIII., who appointed him one of his chaplains; a favour which he afterwards repaid to that monarch, by promoting his divorce from Queen Catharine of Spain, and by his assistance in abrogating the pope's supremacy in England. He was also a great favorite of Lord Cromwell, the secretary of state; by whose recommendation he was sent as ambassador to several courts. Being a man of a bold temper, he was, in 1532, chosen as a fit person to go to Rome, along with Sir Edward Carne, to apologise for Henry's non-appearance upon the pope's citation; and, in the following year, he was again sent to Rome, to deliver his sovereign's appeal to the next general council, from a sentence of excommunication pronounced by the pope against Henry on account of his divorce. On that occasion, Bonner demanded an audience of the pope, and executed his sovereign's commission so rudely, that the pope threatened to cause him to be thrown into a cauldron of melted lead: upon which he thought proper to make his escape. Having returned to England, and being at that time in high favour with the reformers, he was, upon their application, promoted, first to the see of Hereford, and next to that of London; which they found reason afterwards deeply to regret, when he became a most violent enemy of the Reformation.

He was ambassador at the court of Charles V., in 1547, when Henry died; and although, during that reign, he had appeared very zealous against popery, and had strenuously supported all the measures of his sovereign for abrogating the pope's supremacy, yet his subsequent

conduct showed, that he had had his own preferment solely in view; for, in that same year, on the accession of young Edward VI., he refused to take the oaths of abjuration and allegiance, and entered a protest against the king's injunction, and against the homilies. For this he was committed to Fleet prison; but having submitted and recanted, he was released. He now saw, that it would be necessary for him to give a public compliance with the measures taken to advance the Reformation, while, privately, he did every thing in his power to counteract them. He was summoned before the privy council, and admonished; but, as his after conduct clearly evinced, that he supported the church of Rome, and that he despised the king's authority, commissioners were appointed to proceed against him; and, after a long trial, he was committed to the Marshalsea, and deprived of his bishoprick. Bishop Burnet remarks, that, on his trial, he behaved more like a madman than a bishop.

On the accession of Queen Mary, in 1553, he was restored to his bishoprick; and, the following year, he was created vicegerent and president of the convocation, in the room of Archbishop Cranmer, who was committed to the Tower. The persecution which arose against the reformers, now gave him an opportunity of gratifying his cruel and vindictive temper; and he directed all his power and influence against them in the most malignant and violent manner. He obtained a commission for searching out and punishing all heretics, and for erasing from the public records all the proceedings of Henry VIII. against the pope, and particularly the accounts of the visitations of the monasteries, and the renunciation of the papal authority by the monks. He dismissed many of the reformed bishops; and set up mass in St Paul's, even before the act for restoring it was passed. In the short space of about three years, from the beginning of the year 1555 to the year 1558, it is said, that he caused no fewer than two hundred persons to be committed to the flames; besides many who, by his orders, were imprisoned, publicly whipped, and cruelly tortured.

After Elizabeth succeeded to the crown, in 1558, the face of affairs, with regard to religion, was completely changed. Bonner, however, (although it was well known that Elizabeth would espouse the cause of the Reformation,) had the impudence to go with the Protestant bishops to congratulate her upon her accession; but she received him with that cool reserve which he so justly deserved. For some months he was allowed to remain unnoticed; but, in 1559, being called before the privy council, and having refused to take the oaths of allegiance and supremacy, he was again deprived of his bishoprick, and thrown into Marshalsea, where he died in 1569. His body was interred by his friends, in the most private manner, during the night, lest any indignity should have been offered to it by an enraged populace.

Bonner's temper was violent, and his disposition cruel. It is also said, that he was addicted to swearing, and that he sometimes made a prophane use of the Holy Scriptures. His ruling principle was ambition, which led him to sacrifice every thing for the advancement of his temporal interest. Destitute of merit, he raised himself, during the reign of the impetuous Henry, by offering his services to those who were in power, and by making the will of his prince the rule of his conduct; and, in the short but bloody reign of Mary, he perse-

cuted the Protestants with a barbarity, which will for ever render his character and his memory detestable. It has been justly remarked, that it is a clear proof of the lenity of the reformed church, that such a man was permitted to end his days in a prison.

Further particulars of his life may be found in every *History of England*, during the reigns of Henry VIII., Edward VI., and Mary. See also *Biog. Brit.* and Burnet's *History of the Reformation*. (A. F.)

BONNET, CHARLES, an eminent naturalist, was born at Geneva on the 13th March 1720, and was the only son of a Protestant refugee, who sought for shelter in Switzerland from the religious persecutions with which France was at that time agitated. His father sent him early to school; but, in consequence of a defect in hearing with which he was afflicted at an early age, and probably from his being unable to participate in the bustle and rivalry of a public seminary, he made little progress in his studies, and was placed under the care of a domestic tutor, who inspired him with a taste for general literature. In 1736, the perusal of Pluche's interesting work, entitled, *Le Spectacle de la Nature*, turned his attention to those branches of natural history, in the cultivation of which he obtained such distinguished eminence. He investigated with particular success the structure and habits of the curious insect called the *formica leo*, or ant lion, and detected many interesting facts which had escaped the notice of Poupert and Reaumur. He repeated many of Reaumur's experiments on insects. He made several interesting observations on caterpillars; and, at the early age of eighteen, he had the courage to communicate the results of his researches to Reaumur, who admired the ingenuity of young Bonnet, and encouraged him to proceed in the study of natural history. His researches, in 1740, respecting the generation of aphides, or vine fretters, conducted him to a very curious discovery regarding these singular insects. He found, that the impregnation of a female aphid by the male transmitted the prolific quality to its offspring even to the tenth in succession, so that each succeeding female, within these limits, will produce its young without any sexual intercourse with the male.* This discovery was communicated, in a memoir, to the Academy of Sciences at Paris, who immediately ranked its ingenious author among the number of its corresponding members. These experiments were of such a delicate nature, and required such minuteness of observation, and such close attention, that they brought on a weakness of sight, from which he never afterwards recovered.

During these inquiries, Bonnet was prosecuting, with extreme reluctance, the study of the law; a profession to which he had been destined by his father. He continued, however, to perform this unpleasant task till the year 1743, when he received the degree of doctor of laws, on which occasion he abandoned for ever the study of the law. In the year 1741, he discovered, that the reproductive power of the polypus was, in some measure, possessed by different kinds of worms; and, in 1742, he made some new observations on the tape worm, and found that butterflies and caterpillars respired by means of their *stigmata*, or pores. In the year 1743, he communicated to the Royal Society of London a long paper, entitled, *An Abstract of some new Observations on Insects*; the substance of which was republished

in his *Insectologie*, which appeared in 1744, and which contained his observations on worms and aphides. In consequence of this paper, he was elected a member of the Royal Society.

The fatigue which accompanied these incessant labours, produced a severe effect upon his health, and for some time he was compelled to relinquish entirely his favourite pursuits. By this relaxation from study, his eye-sight was considerably improved, and his general health so greatly re-established, that, in 1746, he renewed his studies by a course of experiments on moss and other vegetable substances. These experiments were succeeded by his inquiries respecting the ascent of sap in vegetables, and the action of the upper and under leaves of plants; the result of which were given to the world, in 1754, under the title of *Recherches sur l'usage des Feuilles dans les Plantes*, which was improved by a supplement, in 1779, and afterwards published in the second volume of his works. He published also another treatise on a similar subject, entitled *Sur la Fécondation des Plantes*, which is given in the fifth volume of his works.

From this fertile path of experiment and observation which Bonnet had so long pursued, he was allured, by the study of Malebranche and Leibnitz, into the toilsome but more seducing track of metaphysical speculation. The results of these new inquiries were given to the world in *An Essay on Psychology*, published at London, anonymously, in 1755; and in an *Analytical Essay on the Faculties of the Soul*, which was printed in quarto at Copenhagen, at the expense of the king of Denmark. Both these works were well received; though the latter exposed him to the charge of materialism.

Unable in some measure, both from his studious habits and the defect of his hearing, to participate in the bustle and amusements of active life, he sought in domestic happiness for those comforts which nature had denied him. In 1756, he married one of the family of De La Rive, the aunt of the celebrated Saussure. This lady contributed greatly to the happiness of Bonnet, whom she had the misfortune to survive.

In the year 1762, Bonnet published at Amsterdam, in 2 vols. 8vo, a work entitled, *Contemplations sur les Corps Organisés*. From some misapprehension of the principles which this work inculcated, M. des Malesherbes prohibited it from being sold in France; but the interdict was removed, in consequence of a remonstrance from the author. His next production, entitled, *The Contemplation of Nature*, appeared in 1764, in 2 vols 8vo. This popular and entertaining work, adorned with all the charms of simple eloquence and enlightened piety, was translated into most of the languages of Europe. In 1769, he published at Geneva, in 2 vols 8vo, his *Palingenésie Philosophique*; a work which treats on the past and future state of living beings. To this work he annexed an "Enquiry into the Evidence of the Christian Revelation, and the Doctrines of Christianity," which was published separately at Geneva in 1770, along with a Dissertation on the Existence of God. The German translator of this work dedicated it to a learned Jew, whom he summoned either to refute it, or acknowledge his conviction. Bonnet hearing of this improper challenge, assured the Jew that he was not a party to such a defiance.

The study of natural history having again invited his

* See his remarks *sur les Pucerons*, in his *Traité d'Insectologie*; and in his *Œuvres*, tom. i.

attention, he published in Rozier's Journal a method of preserving insects and fish in cabinets; and in 1774, a paper on the loves of plants, in consequence of his having observed a kind of opening in the pistil of a lily. The other subjects with which he was at this time occupied were, the reproduction of the heads of snails, the water salamander, the pipa or Surinam toad, the manners of bees, the blue colour acquired by exposing mushrooms to the air, and other branches of natural history.

The reputation of Bonnet was now fully established, and he had the honour of corresponding with many of the most distinguished naturalists of Europe. In 1746, he had been chosen a member of the Academy of Bologna, and introduced to the acquaintance of the celebrated Zanotti; and he was, in 1783, elected one of the foreign associates of the Academy of Sciences at Paris. From 1752 to 1768, Bonnet continued a member of the great council of the republic. A love of retirement, however, induced him to withdraw from this active situation, and spend the remainder of his life among the simple pleasures of the country, and in the select society of his friends. His time was chiefly spent in the revision of his works, which appeared in French at Neuchâtel, in 9 vols. 4to, and 18 vols. 8vo. Exhausted with these labours, his health began visibly to decline in 1788, when a dropsy in the chest assailed his constitution. In 1793 it had reached an alarming height, and, after numerous and severe sufferings, he expired on the 20th of May 1793, at the age of 73. A public funeral was decreed to him by his fellow citizens; and his nephew, the celebrated Saussure, pronounced upon him a funeral eulogy.

The talents of Bonnet, though not of the first order, were such as to entitle him to a high rank among the naturalists of the 18th century. His discoveries were useful, but not brilliant; and, if his writings are not distinguished by that depth of thought and acuteness of penetration which indicate a powerful mind, they are marked by an originality of conception, a clearness of illustration, and a simplicity of eloquence, which entitle them to no ordinary praise. The excellence of his private character, the wisdom and moderation of his public measures, and his rational piety and regard for the Christian religion, are qualities which posterity will long admire. BONTIA, a genus of plants of the class Didynamia, and order Angiospermia. See BOTANY. (w)

BONZES, a name given to the priests and devotees of the god Fo, in China, Japan, and Tonquin, and other oriental countries. They are distinguished by different names in the different countries where their superstition prevails. In Siam they are called *Talapoins*; in Tartary, *Lamas*; *Ho-chang* in China; and in Japan, *Bonzes*; by which name they are best known among Europeans. They are exceedingly numerous, and generally live in separate communities, in places wholly consigned to themselves. Splendid apartments are assigned to them in the temples of their god, around which they have rich and extensive domains. Their pagodas are most numerous in the province of Kiang-Nan, where they are agreeably situated, and well endowed. In the north of China, on the other hand, the greater part of these pagodas have fallen into ruins. The island Pon-to, near Chusan, is wholly occupied by bonzes, who lead there a recluse life, like monks in a convent. There are also female bonzes, who attach themselves to particular temples, and, like nuns in the Romish church, take a vow of perpetual celibacy. These devotees worship their divinity under a great variety of forms, representing the different animals into which they suppose him to have transmigrated previous to his deification. Quadrupeds, birds, reptiles, and the vilest animals, had temples, and became objects of public veneration; because the soul of the god, in his transmigrations and metamorphoses, might have inhabited their bodies. See Grozier's *China*, vol. ii. p. 218.

If we may credit the accounts given of them by the European missionaries, the bonzes are the most odious set of impostors that ever disgraced the priestly character. The hatred which these missionaries naturally entertained against a set of Pagan priests, who were the most violent adversaries of the Christian faith, renders it necessary, indeed, to regard their representations with some suspicion. Yet, after every fair allowance that can be made for the exaggerations of prejudice, it is impossible to contemplate the character of the bonzes, without feeling horror for their crimes, and a mingled emotion of contempt and compassion for the credulous and ignorant people who are the dupes of their knavery. Among the precepts which they enjoin on all the faithful votaries of Fo, they inculcate, with particular eagerness, deeds of beneficence to the bonzes, as the surest means of reaping the full benefit of their prayers and mortifications; obtaining the remission of their sins; and a happy transmigration in a future life. The Jesuits, who declaim so vehemently against these crafty priests, were never half so accomplished in the arts of hypocrisy and fraud. Their ordinary income must be considerable; for they are consulted in all cases of sorcery, which forms an essential part of every public and private deliberation; their advice is taken in the most common affairs of life; and they preside at funerals, and mark out the places of interment suitable to the deceased. From this last office they derive considerable emoluments; for there is generally a secret understanding between them and the proprietors of the ground, who share the spoil. Not content, however, with these regular means of subsistence, they have recourse to the lowest and most unwarrantable tricks, for the purpose of extorting money from the superstitious. "We sow," says M. de Guignes, "at Hang-Tchedu-Fou, upon the borders of

the lake Sy-Hou, a pagoda, which contained five hundred gods. The emperor Kien-Long, then living, was of the number; and it cannot be doubted, that this deification was advantageous to the pagoda, for it was in the best condition. The bonzes shewed us a well, into the bottom of which they let down a light, to discover to us the trunk of the tree of which the pagoda was constructed. This miraculous tree renewed its branches all the time necessary for the construction of the edifices, and ceased to grow as soon as they were finished."

Many of them, who have not the address to extort presents by their knavery, endeavour to procure them by the humbler method of exciting compassion by the penances and mortifications which they voluntarily undergo. Sometimes they appear in the squares and public places dragging large and massy chains, which are fastened round their necks and legs; sometimes they mangle their bodies, and cut their flesh with hard flints till they stream with blood; and sometimes they carry burning coals upon the tops of their naked heads. In this situation, they go about from door to door: "You see," say they to those whom they supplicate, "what we suffer, that we may expiate your sins; can you be so hard-hearted as to refuse us a small pittance?" Father Le Comte mentions a very extraordinary penance, of which he was an eye-witness. A young and handsome bonze, of the most insinuating address, stood erect in a kind of narrow chair, stuck full of sharp nails, pointed in such a manner that he could not move without being wounded. He was conveyed slowly from house to house, and endeavoured to excite the compassion of the people, by declaring, that he had shut himself up in that chair for the good of their souls, and resolved not to quit it till they had purchased all the nails, the number of which exceeded two thousand. Each of these nails, he assured them, would prove a source of numerous blessings to them and their families; and even to purchase one, would be an act of heroic virtue.

Yet all these devices are trifling and harmless when compared with the enormities of which they are often guilty. When any person is so audacious as to provoke them, by withstanding their petitions, or refusing to be duped by their impostures, their diabolical revenge can seldom be satiated without the murder of the unfortunate offender. A mandarin passing with his retinue along the highway, observed an immense concourse of people, and, on coming up to them, found that the bonzes were celebrating an extraordinary festival. On a large theatre was constructed a very high machine, surrounded by a small balustrade, above which a young man put forth his head, rolling his eyes in a very wild and frightful manner. The rest of his body was entirely concealed. In the mean time, an old bonze harangued the people from the theatre, extolling the piety and fortitude of the youth, who had resolved to sacrifice his life to Fo, by throwing himself into a deep rivulet which flowed along the side of the highway. The mandarin expressed his surprise that this heroic young man did not himself explain the motives which induced him to undergo this martyrdom, and requested that he might be permitted to come down in order to converse with him. The bonze, terrified by this proposal, protested, that irreparable evil might fall upon the whole province if the victim opened his mouth. But the mandarin, firm to his purpose, promised to take all the risk of that evil upon himself, and, at the same time, ordered the young man to come down. To this command he replied by a

wild irregular movement of his eyes, which seemed ready to burst from his head. "Observe his agitation," cried the bonze, "and judge from that of the injury you do him; already he is sinking under despair, and if you persist he will certainly expire through grief." In spite of these remonstrances, the mandarin commanded his attendants to mount the theatre, and to bring down the young man by force. They found him closely bound and gagged; and no sooner had he recovered his speech, than he demanded immediate vengeance upon the execrable bonzes, who had seized him before break of day; bound him to the machine in such a manner that he could neither move nor speak; and determined to throw him into the river, and to perform their detestable mysteries at the expense of his life. The mandarin ordered the old bonze himself to be thrown into the stream; and the rest of them were carried to prison, and afterwards punished as their atrocities deserved.

With all their pretended sanctity and austerity, too, these infamous wretches are no less voluptuous and profligate than they are selfish and cruel. Instances of their lewdness are mentioned by creditable writers, the recital of which would disgust the least delicate of our readers. In short, in the black catalogue of human crimes there can scarcely be found one which does not disgrace the character of the bonzes. Hence the Chinese, though one of the most superstitious nations in the world, generally hold the bonzes in contempt and abhorrence. It is partly the cause, and partly the effect of this contempt, that the numbers of the bonzes are recruited from the dregs of the people. They purchase young children, whom they early initiate in their mysteries, and in all the arts of deception. These in time succeed them, and in like manner transmit their knowledge and depravity to another generation. In general they are so ignorant, as to be unable to explain the true doctrines of their sect. Though subject to no regular hierarchy, they acknowledge superiors, whom they call *ta-ho-chang*, or grand bonzes. This rank entitles those who have obtained it to particular distinctions, and to the first place in all religious assemblies. There are bonzes of all conditions. Some are employed only in collecting alms; others, more eloquent and better informed, are commissioned to visit the literati, and to insinuate themselves into the houses of the great; and others, venerable for their age and grave deportment, endeavour to ingratiate themselves with the fair sex, and preside in the female assemblies, which are held in several of the provinces. These religious assemblies are the source of considerable gain to the bonzes. They are composed of fifteen, twenty, or thirty ladies, most of whom are of some rank, and advanced in life, or rich widows. One of these ladies is elected superior for the space of a year, and at her house all the assemblies are held. Each of the members contributes towards the expence occasioned by ornamenting their oratory; by the celebration of certain festivals; and the assistance of the bonzes.

For the religious tenets and ceremonies of the bonzes, see CHINA. See also Grozier's *General Description of China*, vol. ii.; Du Halde's *China*, vol. i.; Le Comte's *State of China*; and Barrow's *Account of Lord Macartney's Embassy to China* (k)

BOODH. See BUDDHA.

BOOK may be defined, a work composed for the purpose of communicating the knowledge or ideas of its author, on any subject, and with any design. The im-

mense variety of topics which human knowledge embraces, and which reason or fancy may suggest, renders it necessary, for the sake of precision, to distinguish books by different names, according to the objects proposed by them, or the matters which they discuss. Some of these names are specific and appropriate substantives, as romance, poem, novel, history, journal, &c.; while others are merely general appellatives, applicable not to books alone, but to every thing connected with the subject or science from which these appellatives are derived,—as philosophical, theological, metaphysical, mathematical, or chemical. It is necessary likewise to express, by particular names, the various sizes and forms in which books appear; and hence arise the distinctions of folio, quarto, octavo, &c. Short and fugitive pieces are denominated pamphlets, in contradistinction to books, which are of greater length, and embrace more general or more permanent topics.

The origin of books may be traced to as remote antiquity as the manner of expressing thought by alphabetical or hieroglyphic characters. Their form, and the materials of which they were made, varied with the local circumstances of different nations, and their progress in the arts. The etymology of the word *book*, and its equivalent in many languages, indicates that they were originally written on vegetable substances; such as the rind or bark of trees, the leaves of plants, or on tablets of wood. Thus, from the Latin words *liber* and *codex*, we learn, that books were sometimes inscribed on the inner bark, and sometimes on boards cut out of the main body of the tree; and the English word *book*, derived from the Saxon *boc*, the root of which is the northern *buech*, a beech or service tree, evidently shews that the books of our ancestors were of a similar fabric. The custom of making books of bark still continues in several nations which have made but little progress in refinement. A very curious library of this description was discovered some time ago by the Russians among the Calmuc Tartars. The books were exceedingly long and narrow; the leaves very thick, and made of barks of trees, smeared over with a double varnish; the ink, or writing, was white on a black ground. Copies of the Gospels in the Malay tongue are occasionally brought to this country written on oblong slips of bark, fastened together by a cord. The Egyptian papyrus, too, which was first manufactured into paper, was in very common use among the ancients, about the time of Alexander the Great; but as these vegetable materials were of too frail a nature to be long preserved, it was found necessary to have recourse to some substance which might be less liable to be destroyed by accident, or to decay with time. Leather, made of the skins of goats or sheep, was accordingly employed for this purpose; and successive attempts to remedy the imperfections of that substance, gave rise to the invention of parchment. The manufacture of skins into parchment is said to have been first invented at Pergamus, when the exportation of the papyrus from Egypt was prohibited by one of the Ptolemies, in order to throw an obstacle in the way of Eumenes, King of Pergamus, who endeavoured to rival him in the magnificence of his library. Most of the ancient manuscripts now extant are written on parchment, and scarcely any of them on the papyrus. There are to be seen, in some libraries on the continent, manuscripts written on a kind of parchment manufactured from the human skin; these manuscripts are supposed to come from Peru. Books have sometimes

likewise been engraved or stamped upon lead, and written or printed on silk, linen, horn, vellum, and paper. The manufacture of paper is an invention of so late a date as the thirteenth or fourteenth century. The different materials which have been employed in this manufacture will be more properly described under the article PAPER. At present, we shall only observe, that the attention of the curious was long directed towards the discovery of a substance susceptible of writing, and proof against fire. Professor Burkman, of Brunswick, published a treatise on the manufacture of linen from asbestos, and is said to have caused several copies of his work to be printed on paper fabricated from linen of that description. Signior Castagnatta, too, in his account of the asbestos, proposes a scheme for making a book of so unperishable a nature, as to merit the appellation of the *Book of Eternity*. The leaves of this book were to be of asbestos paper, the covering of a thicker texture, but fabricated from the same substance, and the whole to be sewed together with asbestos thread. The contents of it were to be written in letters of gold, so that the whole materials, being not only incombustible but proof against all the elements, must remain for ever undestroyed.

The form of books seems to have been originally square, to which we find frequent allusions in Scripture, under the appellation *sephir*, translated by the Septuagint *αζήρες*, square tables. When they came to be written on flexible materials, they were rolled up in scrolls, called by the Greeks *ρολλοίαι*, and *rotulæ* by the Romans. Only one side of the paper, or parchment, was written upon, and one sheet was always joined to the end of another, till the volume, or book, was finished, when it was rolled up on a cylinder, or staff. To each end of this stick was affixed a ball, or knob, which was employed as a handle for evolving the scroll. These balls were called *umbilici*, or *cornua*, and were generally made of bone, wood, or horn, and often carved and adorned with ivory, silver, gold, or precious stones. Only one book was included in a volume, so that a work generally consisted of as many volumes as books. On the outside was generally written the title, *Συλλαβος*.

In the Oriental countries, it is customary not only to roll up their books in the manner which we have described, but to wrap them in an elegant and costly covering, and to inscribe on the covering a title indicating the general tenor of their contents. This custom of writing on the outside of the covering of a book, or letter, has led Chrysostom to suppose, that, in the passage of the 39th Psalm, which our translators have rendered, "In the *volume* of the book it is written of me," the word translated volume was the wrapper in which the sacred book was contained; and that on this wrapper was inscribed a title, which signified "the coming of the Messiah." This interpretation suggests a much more distinct idea than the English word volume; for, as every Hebrew book was in reality a roll, or volume, the passage according to our version, merely signifies, "In the book it is written of me." But, when we refer it to the case in which the book was inclosed, the expression becomes clear and energetic, implying, that the sum and substance of the sacred book is, that "the Messiah cometh;" which title might, with great propriety be inscribed on the wrapper or covering of these sacred writings.

In another translation this expression is rendered *εν τωμο*, which seems to intimate, that the motto was

inscribed on the cylinder, round which books of the form we have been describing were rolled. In general, the cylinder extended far enough beyond the parchment, paper, or writing material, to exhibit conveniently, by a title, the general purport of the volume. In illustration of this idea, Mr Harmer, in the fourth volume of his *Observations on Scripture*, mentions a circle of gold, with the name of one of our Saxon princes inscribed upon it, and ornamented after the rude manner of those times, which, he supposes, might be designed to ease the end of the cylinder, on which some book belonging to that monarch, or relating to him was rolled. Of this ancient piece of gold there is an engraving in the seventh volume of the *Archæologia*, or *Transactions of the Antiquarian Society*. The square form, composed of separate leaves, which is now universal in Europe, is said to have been first invented by one of the kings of Pergamus; and soon came into general use. We are assured by Montfaucon, that, of the numerous Greek manuscripts which he had seen, only two were in the form of rolls, the rest were made up much in the same manner as modern books.

The internal arrangement of books has varied considerably in different countries, and at different periods. At first the letters were only separated by lines, and it was long before their separation into individual words was even thought of. While this mode of writing prevailed, the utmost care was necessary to guard against errors; and accordingly we are informed, that the Rabbin, who were particularly anxious for the purity of the sacred text, knew the exact number of letters which a book contained. The inconvenience of this mode of writing suggested the division of letters into separate words; and the love of precision, by degrees, introduced the practice of noting these words with accents, and distributing them, by different points and marks, into periods, paragraphs, sections, and chapters. In Hebrew, and other oriental books, the lines run from right to left; the Northern and Western nations write from left to right; the Greeks followed both directions alternately, going in the one, and returning in the other; in Chinese books, the lines run from top to bottom. The conclusion of a book was anciently marked with a figure \sphericalangle , called *coronis*; and the whole book was sometimes washed with cedar oil, or strewed between the leaves with citron chips, to prevent it from rotting. Certain formulæ were occasionally used at the beginning and end of books; thus we find, at the end of the books of *Exodus*, *Leviticus*, *Numbers*, *Ezekiel*, the word נְחִיָּם , be courageous, as if to exhort the reader to persevere, and proceed to the following book. Books were often guarded, likewise, at the conclusion, with imprecations against such as should falsify them; as we find in the *Apocalypse*. It is with a similar view that the Mahometans place at the beginning of all their books the name of God, which is regarded with such profound reverence, as to afford the most certain protection to every thing on which it appears.

Before the invention of printing, and of the manufacture of paper from linen, books were so scarce and dear, as to be without the reach of all but persons of considerable opulence. Though the materials of which they were made had been as cheap and as plentiful as paper is at present, the labour of multiplying copies in manuscript would always have kept their numbers comparatively scanty, and their price high. Hence, in all the nations of antiquity, learning was almost exclusively con-

finied to people of rank; and the lower orders were only rescued from the darkness of total ignorance, by the reflected light of their superiors, and raised above the rudeness of barbarism, by that partial improvement which men of cultivation and refinement necessarily impart, in a greater or less degree, to all within the sphere of their influence. The papyrus being the cheapest material for writing, was, of course, in most general use. But when the Saracens had conquered Egypt, in the seventh century, and the connection between that country and Europe was entirely broken off, the papyrus could no longer be procured, and books, already sufficiently rare, became now almost unattainable. Parchment, the only substance for writing which then remained, was so difficult to be procured, that it was customary to erase the writing of ancient manuscripts, to make room for some other composition. In this manner, many of the best works of antiquity were lost for ever; the noblest effusions of Cicero, or Virgil, might be exchanged for the barbarous jargon of a monkish declaimer; and the elegant and instructive narrations of Livy and Tacitus might be lost, for the superstitious detail of pretended miracles, or the legendary story of a saint. History records many facts which place in a very striking light the scarcity, and consequent value, of books, during the dark ages. Private persons seldom possessed any books at all; and even distinguished monasteries could, in general, boast of no more than a single missal. Towards the end of the seventh century, even the papal library at Rome was so poorly supplied with books, that Pope St Martin requested Sanciamand, bishop of Maestricht, to supply this defect, if possible, from the remotest parts of Germany. Nearly two centuries after, Lupus, abbot of Ferrieres, in France, sent two of his monks to Pope Benedict III. to beg a copy of *Cicero de Oratore*, and Quintilian's *Institutes*; "for," says the abbot, "although we have part of these books, there is no complete copy of them in all France." John de Pontissara, bishop of Winchester, on borrowing from his cathedral convent of St Swithins, at Winchester, (in 1299) a Bible with marginal annotations, in two folio volumes, gave a bond for the return of it, drawn up with great solemnity. For the bequest of this Bible, along with 100 marks, the monks were so grateful, that they appointed a daily mass to be said for the soul of the donor. To present a book to a religious house, was thought so valuable a donation as to merit eternal salvation; and it was offered on the altar with great ceremony. Books were sometimes given to monasteries, on the condition that the donor should have the use of them for life; and sometimes to private persons, with the special injunction, that they who received them should pray for the souls of their benefactors. The prior and convent of Rochester, threatened to pronounce every year the irrevocable sentence of damnation on the person who should dare to purloin or conceal a Latin translation of Aristotle's *Poetics*, or even obliterate the title. Roger de Insula, dean of York, presented several Bibles to the University of Oxford, in the year 1225, with this provision, that every student who perused them should deposit a cautionary pledge. So late as the year 1300, the library of that university consisted of only a few tracts, chained or locked in chests, in the choir of St Mary's Church. One of the statutes of St Mary's College, in Oxford, (1440) enacts, that no scholar shall occupy a book in the library more than an hour, or two hours at most, so that others shall be hindered from the

use of the same. A more striking proof could not be adduced of the paucity of books which the library then contained. The celebrated library established by Humphrey, duke of Gloucester, in the same university, did not contain more than 600 volumes. In the beginning of the fourteenth century, the only classics in the possession of the University of Paris were, single copies of *Cicero*, *Ovid*, *Lucan*, and *Boethius*.

Some idea of the extravagant price of books in these ages of ignorance, may be formed from the following well authenticated facts: *The Homilies* of Bede, and St Austin's *Psalter*, were purchased, in the year 1174, by Walter, prior of St Swithins, at Winchester, from the monks of Dorchester, in Oxfordshire, for twelve measures of barley, and a splendid pall, on which was embroidered, in silver, the history of St Birinus converting a Saxon king. About the year 1400, a copy of John of Meun's *Roman de la Rose*, was sold before the palace gate at Paris for 40 crowns, or 33*l.* 6*s.* sterling. For a copy of the *Homilies* of Haimon, bishop of Halberstadt, the countess of Anjou gave 200 sheep, five quarters of wheat, and the same quantity of rye and millet. When Louis XI. of France borrowed the works of Rhasus, the Arabian physician, from the medical faculty at Paris, (so late as the year 1471,) he not only deposited by way of pledge a considerable quantity of plate, but was obliged to find a nobleman to join with him as surety in a deed, binding himself, under a great forfeiture, to restore it.

The manufacture of paper from linen, afforded such facilities for the multiplication of manuscripts, as produced a very great reduction in their price, and, of course, contributed essentially to the diffusion of knowledge. Learning had already begun to revive, and to be cultivated with considerable ardour, when the invention of printing, about the middle of the fifteenth century, gave a new stimulus to the human mind, and formed the most important æra to the history of literature and civilization. The power of increasing indefinitely the number of books, now placed them within the reach of persons of the most moderate fortunes; the avenues of science were thus thrown open to any one who had the curiosity to enter them; and its mysteries became accessible to all who had the perseverance to proceed. For some time after this happy invention, it was allowed to produce its natural effects; and the reading part of the community, delighted with the advantage of perusing their favourite authors at an easy rate, never thought of undervaluing a book on account of the facility of procuring it, as if learning could become less precious by being generally diffused. By degrees, however, the fastidiousness induced by plenty began to manifest itself, even in the appreciation of works of literature; the natural ambition of possessing what few could obtain, inspired the wealthy and the curious with a kind of contempt for books, however excellent in themselves, which were rendered common by their cheapness, and gave to others, which neglect or other causes had now rendered scarce, an adventitious value, often in inverse proportion to their intrinsic worth. Were the passion for rare books confined to those alone whose merit makes them desirable, it would be equally useful and respectable. But when it delights in raking up from just oblivion, at any trouble or expense, works which no man of taste or judgment would wish to open, it surely deserves no gentler appellation than drivelling and folly. That the majority of rare books are rare, only because they are destitute

of merit, is obvious from this consideration, that new impressions of them would certainly have been printed, if there had been any hopes of their being sold; yet there are others, not so despicable, which particular circumstances have prevented from finding general circulation, and which, therefore, have become the objects of a very allowable, and even laudable curiosity. It may not be improper here to mention, some of the causes of the scarcity of particular books; in enumerating which, we shall be led to relate some very curious facts in the history of modern literature.

Bibliographers have classed rare books under two general heads, those whose scarcity is *absolute*, and those of which the scarcity is only *relative*. Under the first head are comprehended,

1. Books of which only a very small impression was originally printed, and of which the impression, from particular circumstances, could not be renewed. One of the earls of Bute published a botanical work in eight volumes, with coloured plates, the impression of which he is said to have limited to twelve copies. Some additional copies, however, seem to have been surreptitiously printed; for one with uncoloured plates was lately offered to sale; for which, though imperfect, forty guineas were demanded. The twelve original copies were distributed as presents. In the year 1807, a work entitled *Views in Orkney*, by the Marchioness of Stafford, was printed for private distribution only. The large paper copies of the Grenville Homer were likewise intended solely as presents; and when they come accidentally to sale, are valued at one hundred guineas. The *Antichita d'Ercolano*, a splendid work in nine folio volumes, was printed at the expense of the king of Naples, and presented to illustrious individuals, or to distinguished literary bodies; and a translation of Sallust by Don Gabriel, one of the princes of Spain, and, we think, of the same family, was printed in a beautiful Italian character, and distributed in a similar manner. But none of these works can be compared with the *Museum Worsleyanum*, which consists of two large folio volumes full of engravings. It was printed in 1794, and the prime cost of each copy was estimated at 300*l.* sterling. It was wholly disposed of in presents by its munificent author, sir Richard Worsley. A small work entitled *Museum Typographicum*, was published by *Debure*, who is said to have limited the impression to twelve copies; and Fournier, a French bibliographer, printed only twenty-five copies of his *Essai Portatif de Bibliographie*.

2. The second cause of the absolute scarcity of books is, when they have been very rigorously suppressed. However we may regret any restrictions on the liberty of the press as unfavourable to the evolution of the human powers, and the progress of liberal knowledge, we must at least allow it to be natural for every government, to oppose the promulgation of any doctrines or principles which appear to have even the remotest tendency to undermine its civil or religious institutions. In our own country, works so directly subversive of every thing sound in policy, and sacred in religion, are published under the shelter of the freedom of the press, that we are sometimes tempted to wish for the interposition of the civil government to repress this licentiousness, till we are reminded, by the example of other nations, how fatally such interposition might tend to repress at the same time all free inquiry, and, instead of promoting the influence of morality or of genuine philosophy, to be perverted into the instrument of public oppression, or

of private revenge. In the *Indices Expurgatorii* of Roman Catholic countries we see many books condemned, which contain such treasures of learning, and exhibit so enlightened and liberal views of every subject which they discuss, as command the admiration of all the unbiassed and judicious. Who can hear, without emotion, that the works of such men as Linnæus, and our countryman Principal Robertson, men not more remarkable for the vigour of their genius, and the amplitude of their attainments, than for their sacred regard to religion, are prohibited, on the continent, as dangerous in their tendency? The slightest appearance of contradiction, even though unintended, to the absurdities of a prevailing superstition, has often drawn down the weightiest vengeance on the unfortunate authors. A printer was beheaded in 1542, for the publication of a Dutch Bible. Papebrock, a learned Jesuit of Antwerp, was condemned by the Inquisition of Madrid, for advancing three heterodox assertions; first, that the Carmelite, or bare-footed monks, were not descended from the prophet Elias; secondly, that the image of our Saviour was not impressed on the sacred handkerchiefs, and that doubts might be entertained whether there was actually a Saint Veronica; and, lastly, that the church of Antwerp was not, as it pretended, in possession of that corporeal evidence which proved the circumcision of Jesus Christ. After these examples of intolerance, we cannot be surprised that the truly exceptionable works of Voltaire should have been condemned and suppressed immediately on their publication; that the *Emile* of Rousseau was torn and burnt by the hands of the common executioners at Paris and Geneva; and that the same sentence was passed against the *Christianisme Devoué* of Boulanger by the French parliament in 1770, and against the *History of the East and West Indies* by the Abbé Raynal in 1781. Even in the literary history of our own country, many instances occur of persecution equally unjustifiable against authors, whose publications have been offensive to church or state. William Prynne, the celebrated author of *Hestriomastix*, a work levelled against the licentious amusements and practices which prevailed in the court of Charles I., was committed to the Tower of London in 1633, the year after its publication, and sentenced by the Star Chamber to pay a fine of 5000*l.* to the king; to be expelled from the university of Oxford, and the Temple in Lincoln's Inn; to be degraded and disabled from practising his profession as a lawyer; to stand on the pillory; there to lose part of his ears; to have his book burnt before his face; and to be imprisoned for life. The execution of this severe sentence did not deter him from again exposing himself to the vengeance of the court, by the publication of another work, entitled *News from Ipswich*, which made its appearance in 1637. He was a second time sentenced by the Star Chamber to pay a heavy fine, to lose the remainder of his ears on the pillory, to be branded on both cheeks with the letter S. L. (Schismatical Libeller,) and to be perpetually imprisoned. This sentence was enforced in all its rigour; but when the government was overturned by the revolutionists, he was relieved by an order of the House of Commons in 1640; and twenty years after was himself elected a member of parliament. Neither prosperous nor adverse fortune, however, could check his propensity to expose and inveigh against what he conceived to be abuses; and he now published some reflections against the House; for which he was compelled to apologise. Woolston, the author of several

controversial works in theology, was prosecuted in the Court of King's Bench, for the publication of the *Moderator and Apostate, with two Supplements*. At the solicitation of Mr Whiston, the attorney general then desisted from the prosecution. But when he published his *Six Discourses on the Miracles of Christ*, a new prosecution was commenced against him, and he was fined in 1701, and sentenced to one year's imprisonment. Coward's *Thoughts on the Human Soul*, published at London in 1702, were condemned by parliament to be burnt by the hands of the common executioner, as containing doctrines hostile to the Christian religion; and the famous John Wilkes was expelled from parliament, in consequence of the publication of his *North Briton*, and *Essay on Women*. While the question of the expediency of a union between England and Scotland was keenly agitated, Atwood, an English lawyer, imprudently revived the obsolete dispute concerning the superiority of England over this kingdom. A treatise which he wrote on this invidious subject, was communicated to the Scottish parliament, who, with becoming indignation, condemned it to be burnt in Edinburgh by the common executioner. Works suppressed from such causes as these, often excite an interest which leads in time to their extensive circulation; but at all events, the original editions of them necessarily continue exceedingly rare; and when a portion of them has been destroyed, the scarcity must always remain. In some instances, the most rigorous suppression becomes not only justifiable, but indispensably necessary, as in the case of works directly immoral, or of malicious libels calculated to ruin the character and the peace of individuals. Yet such is the perverseness of human nature, that such works are frequently read with an avidity exactly proportioned to the severity with which they are prohibited. Two volumes by Pasquill, published at Rome in 1544, are now very eagerly sought after, and bear an extraordinary price. They contain a number of epigrams in verse, and dialogues in prose, inveighing with much asperity against the government, and the conduct of private persons.

3. The next cause of the scarcity of books is, when, by particular accidents, they have been almost wholly destroyed. It is owing to a cause of this nature, that the *Atlantica* of Olaus Rudbeck can scarcely be obtained complete; and had not some copies of the second part of the *Machina Cælestis* of Hevelius been given to the author's friends, it would have been totally lost in the flames which consumed his house. A similar accident destroyed most of the large paper copies of Wakefield's *Lucretius de Natura Rerum*; in consequence of which those which were preserved are valued at sixty guineas each.

4. A fourth cause of the absolute scarcity of books is, when only part of them has been printed, the rest remaining unfinished. Cases of this kind too frequently occur, to require or to permit any particular enumeration. It necessarily happens when an author or editor, for want of encouragement, is unable to proceed with his work; and as none but an amateur of rarities would take the trouble of rescuing such fragments from total destruction, these unfinished productions become, of course, the scarcest of books.

5. The next class of books which are absolutely scarce are, those which are printed on very large paper, or on vellum paper. The copies of a work printed on paper of this description, are in general very few, and their

great expense would at any rate prevent them from becoming common. Strength and beauty of paper, and ample extent of margins, are qualities so much valued by some curious collectors, that they will scruple at no price to obtain them. A stern philosopher will be disposed to ridicule that taste which prizes a book merely for the blank space which it contains, and the size of the type, or the stiffness of the paper; and will be contented to enjoy the *accuracy* of a Grenville Homer for thirty shillings, leaving more wealthy or more passionate amateurs to pay 100 guineas for its greater magnitude, and more splendid dress. We should be little disposed, for our own parts, to regret or to censure this passion for royal paper, and wide margins, had it not become so fashionable among booksellers to publish every new work in this expensive manner, as if they wished those days to return when reading was the exclusive privilege of the opulent, and the repositories of learning remained shut against all who did not possess the golden key.

6. The next cause which we shall mention of the absolute scarcity of books is, their being printed on vellum, or any other substance besides paper. We have already mentioned some of the other materials employed for writing previous to the invention of printing, or in modern nations where the invention is unknown. Books formed of such materials must always be highly prized by the curious bibliographer, both for their great rarity and singular texture. Next to these in value, as well as in scarcity, are books printed in vellum, the expense of which is so great, that very few vellum copies of any work have ever been prepared. So far as we know, there is not a single instance of a whole impression of any work having been printed on this beautiful but costly substance. Hence books on vellum have generally been esteemed as the most precious treasures of a library; and there are instances of their being transmitted to successive generations, as one of the most important articles in a family property. One of the most beautiful specimens of vellum printing is a Roman breviary printed at Venice in 1478. It is a large folio volume, consisting of 401 leaves. The vellum is of the finest quality, thin and remarkably white, and the typography so smooth and well defined as to vie with the most beautiful impression from copperplate. It is printed in black and red ink, and decorated with splendid illuminations in gold, and different vivid colours; and with paintings of different animals. Whole pages occur in red ink, which has no gloss; but the black ink is extremely deep, and shines as if varnished. A few months ago, the Faculty of Advocates purchased a copy of this breviary for 100 guineas. Another very elegant work, of a similar description, entitled *Heures à l'usage de Rome*, was printed on vellum in 1507, or 1527. It is a small folio, consisting of 115 leaves, each page encircled by engravings on wood in great profusion, and, for the period of its appearance, extremely well executed. A work of Petanius was likewise published on vellum in 1610, consisting almost entirely of engravings, with a small portion of text on each plate. It is divided into two parts; the first, entitled *Supellectilis Portuicula*; the second, *Veterum Nummorum*. Those works are necessarily so rare, that they are very seldom to be met with. But there are to be found in public libraries, as well as in private collections, copies of the classics printed on vellum, which are held in very high estimation. Most of these copies were printed on the con-

tinued in the fifteenth and sixteenth centuries. A specimen of this kind of typography, executed by Caxton, the first English printer, is to be seen in the King's library.

The practice of printing on vellum was almost wholly relinquished for many years, probably on account of its great expense; but was recently revived in several of the countries of Europe. Though modern works of this description are said to be inferior in beauty to those of greater antiquity, still they are very highly valued, and bring an extraordinary price. Goldsmith's and Parnell's Poems, and the Economy of Human Life, were printed on vellum in 1804, and sold for fifteen guineas each. Three copies of Lewin's British Birds were printed on vellum in 1796; one of which the author tore to pieces in a frenzy of passion, and each of the remaining two was sold for 140 guineas. This kind of printing seems to have been introduced into our native country at a very early period. So far back as the year 1536, Bellenden's translation of Hector Boethius's History of Scotland was printed on vellum, in a folio of 259 pages. Four copies of this work are known to exist in Scotland; one in the university of Aberdeen, another in that of Edinburgh, and two in the possession of private individuals. Vellum printing was revived in Edinburgh in 1809, when a beautiful specimen was produced in a small volume called *Monastic Antiquities*. M. Van Praest is now engaged in framing a list of all the works that have been printed on vellum, of which he has been able to enumerate above 2000. For farther particulars respecting the different materials of which books have been made, and the various styles of printing them, we must refer to the articles PAPER and PRINTING.

We cannot let slip this opportunity, however, of mentioning a very remarkable book, neither written nor printed, entitled *Liber passionis Domini Nostri Jesu Christi, cum figuris et characteribus nulla materia compositis*. For this very singular bibliographic curiosity, Rodolphus II. of Germany offered 11,000 ducats, in the year 1640. It consists of the finest vellum; the whole letters of the text are cut out of each folio; and, being interleaved with blue paper, it is as easily read as if it had been printed. It lately belonged to the family of the Prince de Ligne, and is at present in France; but as it bears the royal arms of England, it appears extremely probable that it is an English production.

The last description of books which are absolutely scarce, are manuscripts, written either before or after the invention of printing. Such original manuscripts form the chief riches of libraries. They are generally written on vellum; and, independent of their antiquity and rarity, cannot fail to be prized for the miniatures and golden letters with which they are adorned, and the excellent order in which they are preserved.

Under the second class, or books of *relative* scarcity, are comprehended such as excite little interest, or are too extensive for the purchase of individuals. Under this head, therefore, we may class, 1. Great works, such as the *Acta Sanctorum*, the *Councils*, the *Grand Library of the Fathers*, the *Bibliotheca Maxima Pontifica* of Rucaberti, and the *Gallia Christiana*, and others of a similar description. 2. Fugitive pieces, the interest of which dies with the occasion which gave them birth. 3. Histories of particular towns, which can be valued properly by the inhabitants alone. 4. Histories of academies and literary societies, the subject of which is too particular to excite general attention. 5. Lives of learn-

ed men, which, like other private histories, excite only a partial and transient interest. 6. Catalogues of public and private libraries, which can be valued only by those who have access to them, and of which, in consequence, only a few copies are printed. 7. Books of pure criticism, which, as they suit the taste of critics alone, who form but a very small proportion of the reading world, are scattered into different countries, and at last become very rare. 8. Books of antiquity, which, being generally adorned with numerous plates of urns, statues, medals, &c. are at first exceedingly expensive, and cannot be reprinted without much difficulty. 9. Books which treat of the curious arts, such as music, painting, and sculpture, which are suited to the taste only of artists or amateurs, among whom, when they are once dispersed, they cannot easily be recovered. The 4th volume of *Bibliothèque des Philosophes Alchymiques ou Hermetiques*, in 12mo, is now so rare, that it is sold for sixty French livres. The cause of this scarcity is, that a thousand copies were printed of the three first volumes, and only five hundred of the fourth. 10. Books written in languages little known, or those whose style is caricatured, or intentionally corrupted.

Particular editions of books likewise acquire great value for their relative scarcity. Of this kind are, 1. Editions printed from ancient manuscripts. 2. The first edition printed in a particular town. 3. Editions which have issued from the presses of celebrated printers. 4. Editions distinguished by any peculiar and extraordinary letters or characters. 5. Editions published in foreign countries. 6. Editions which have never been exposed to sale. 7. Editions which have been sold under different titles. To what an enthusiastic height some bibliographers have carried their fondness for early editions, the following facts will most strikingly illustrate. Ten guineas were paid for four odd leaves of an early edition of some of the works of Cicero. A first edition of Suetonius is valued at 100 guineas, and the Florentine Homer was recently purchased for 95*l.* sterling. The Mazarine Bible was sold in Edinburgh, in 1806, for 150 guineas; and the first edition of Shakspeare, published in 1623, is valued nearly as high.

For further particulars on the subject of books, the reader may consult Peignot, *Dictionnaire Raisonné de Bibliologie*, 3 tom. Peignot, *Dictionnaire des principaux livres condamnés au feu supprimés ou censures*. Peignot, *Essai de Curiosités bibliographiques*. *Dictionnaire Bibliographique*, 4 tom. Paris, 1790—1802. Fournier, *Nouveau Dictionnaire Portatif de Bibliographie*. Clarke's *Bibliographical Dictionary*, Barbier, *Dictionnaire des ouvrages anonymes ou Pseudonymes*. Miglius et Stollus, *Bibliotheca anonymorum et pseudonymorum*. Clement, *Bibliothèque des livres difficiles à trouver*. Haym, *Bibliotheca Italiana*. Deburc, *Bibliographie Instructif*. Bandini, *Catalogus Codicum bibliothecæ Medicæ Laurentianæ*. Heincker, *Idée générale d'une collection d'Estampes*. Panzer, *Annales Typographici*. Mattaire, *Annales Typographici*. Meerman, *Origines Typographici*. Brandolese, *Serie dell' edizione Aldine*. Renouard, *Annales de l'imprimerie des Aldes*. Audiffredi, *Catalogus Romanorum editionum seculi xv.* Harwood, *View of the various editions of Greek and Roman Classics*. Dibdin, *Introduction to the rare and valuable Greek and Latin Classics*. Amos and Herbert, *Typographical Antiquities of Great Britain and Ireland*. Salden, *De usu et abusu librorum*. Bartholinus, *De Libris legendis*. (c) (k)

BOOK-BINDING, the art of sewing together the sheets of a book, and securing them with a back and side boards. Binding is distinguished from *stitching*, which is merely sewing the leaves, without bands or backs; and from *half binding*, which consists in securing the back only with leather, the pasteboard sides being covered with blue or marbled paper; whereas, in binding, both the back and sides are covered with leather.

At what time the art of book-binding was first invented it is impossible to ascertain; but Phillatius, a learned Athenian, was the first who pointed out the use of a particular kind of glue for fastening the leaves of a book together; an invention which his countrymen thought of such importance as to entitle him to a statue. The most ancient mode of binding consisted in gluing the different leaves together, and attaching them to cylinders of wood, round which they were rolled. This is called Egyptian binding; and continued to be practised long after the age of Augustus. It is now wholly disused, except in oriental countries, and in the Jewish synagogues, where they still continue to write the books of the law on slips of vellum sewed together, so as to form only one long page, with a roller at each extremity, furnished with clasps of gold or silver. The square form of binding which is now universally practised, at least in Europe, is said to have been first invented by one of the kings of Pergamus, the same to whom we owe the invention of parchment. See **Book**.

Book-binding, according to the present mode, is performed in the following manner:—The sheets are first folded into a certain number of leaves, according to the form in which the book is to appear; viz. two leaves for folios, four for quartos, eight for octavos, twelve for duodecimos, &c. This is done with a slip of ivory or boxwood, called a folding stick; and in the arrangement of the sheets, the workmen are directed by the catch-words and signatures at the bottom of the pages. When the leaves are thus folded and arranged in proper order, they are beaten on a stone with a heavy hammer, to make them solid and smooth, and then they are pressed. After this preparation, they are sewed in a sewing press, upon cords or packthreads called bands, which are kept at a proper distance from each other, by drawing a thread through the middle of each sheet, and turning it round each band, beginning with the first and proceeding to the last. The number of bands is generally six for folios, and five for quartos, or any smaller size. The backs are now glued, and the end of the bands are opened, and scraped with a knife, that the pasteboard sides may be more conveniently fixed; after which the back is turned with a hammer, the book being fixed in a press between boards, called backing boards, in order to make a groove for admitting the pasteboard sides. When these sides are applied, holes are made in them for drawing the bands through; the superfluous ends are cut off, and the parts are hammered smooth. The book is next pressed for cutting; which is done by a particular machine called *the plough*, to which is attached a knife. It is then put into a press called the cutting press, betwixt two boards, one of which lies even with the press, for the knife to run upon; and the other above for the knife to cut against. After this, the pasteboards are cut square with a pair of iron shears; and, last of all, the colours are sprinkled on the edges of the leaves with a brush made of hog's bristles; the

brush being held in one hand, and the hair moved with the other.

Different kinds of binding are distinguished by different names, such as *law binding*, *marble binding*, *French binding*, *Dutch binding*, &c. In Dutch binding, the backs are of vellum. In French binding, a slip of parchment is applied over the back between each band, and the ends are pasted on the inside of each pasteboard. This *indorsing*, as it is called, is peculiar to the French binders; who are enjoined, by special ordonnance, to back their books with parchment. The parchment is applied in the press, after the back has been grated to make the paste take hold. The Italians still bind in a coarse thick paper, and this they call binding *alla rustica*. It is extremely inconvenient, as it is liable to wear without particular care.

A patent was obtained in 1799, by Messrs John and Joseph Williams, stationers in London, for an improved method of binding books of every description. The improvement consists of a back, in any curved form, turned a little at the edges, and made of iron, steel, copper, brass, tin, or of ivory, bone, wood, vellum, or in short of any material of sufficient firmness. This back is put on the book before it is bound, so as just to cover without pressing the edges; and the advantage of it is, that it prevents the book, when opened, from spreading on either side, and causes it to rise in any part to nearly a level surface. In this method of binding, the sheets are prepared in the usual manner, then sewed on vellum slips, glued, cut, clothed, and boarded, or half-boarded; the firm back is then fastened to the sides by vellum drawn through holes, or secured by inclosing it in vellum or ferret wrappers, or other materials pasted down upon the boards, or drawn through them.

A patent was likewise obtained in 1800, by Mr Ebenezer Palmer, a London stationer, for an improved way of binding books, particularly merchants account books. This improvement has been described as follows: Let several small bars of metal be provided about the thickness of a shilling or more, according to the size and thickness of the book; the length of each bar being from half an inch to several inches long, in proportion to the strength required in the back of the book. At each end of every bar let a pivot be made of different lengths, to correspond to the thickness of two links which they are to receive. Each link must be made in an oval form, and contain two holes proportioned to the size of the pivots; these links to be of the same metal as the hinge; and each of them nearly equal in length

to the width of two bars. The links are then to be rivetted on the pivots, each pivot receiving two of them, and thus holding the hinge together, on the principle of a link-chain or hinge. There must be two holes or more of different sizes, as may be required, on each bar of the hinge or chain; by means of these holes, each section of the book is strongly fastened to the hinge, which operates with the back of the book, when bound, in such a manner as to make the different sections on a parallel with each other, and thus admit writing without inconvenience on the ruled lines, close to the back.

The leather used in covering books is prepared and applied as follows: Being first moistened in water, it is cut to the size of the book, and the thickness of the edge is pared off on a marble stone. It is next smeared over with paste, made of wheat flour; stretched over the pasteboard on the outside, and doubled over the edges within. The book is then corded, that is, bound firmly betwixt two boards, to make the cover stick strongly to the pasteboard and the back; on the exact performance of which, the neatness of the book in a great measure depends. The back is then warmed at the fire to soften the glue, and the leather is rubbed down with a bodkin or folding stick, to set and fix it close to the back of the book. It is now set to dry, and when dry the boards are removed; the book is then washed or sprinkled over with a little paste and water, the edges and squares blacked with ink, and then sprinkled fine with a brush, by striking it against the hand, or a stick; or with large spots, by being mixed with vitriol, which is called marbling. Two blank leaves are then pasted down to the cover, and the leaves, when dry, are burnished in the press, and the cover rolled on the edges. The cover is then glazed twice with the white of an egg; then filleted, and last of all polished by passing a hot iron over the glazed colour. For farther information on book-binding, see Dudin, *Art du relieur doreur de livres. Encyclopedie Methodique*, art. RELIEUR. Williams's *Patent for Book-binding*, in the *Repertory of Arts*, vol. xiv. p. 89. Palmer's *Patent for binding Books with Hinges of Metal*, in the *Repertory of Arts*, vol. xiv. p. 305; and Hardy's *new Cutting Press for Bookbinders*, in the *Transactions of the Society for the Encouragement of Arts, &c.* vol. xxiv. p. 116. (k)

BOOK-CASES. An account of a new and improved bolt for book-cases, invented by Mr Herbert, will be found in the *Transactions of the Society for the Encouragement of Arts*, vol. xxiii. p. 313. (w)

BOOK-KEEPING.

BOOK-KEEPING, is the history of public or private property in all its changes; and of the causes of these changes, and of the increase or decrease of property following from them.

The general history of property, written in the order of time, is called the *Waste-book*: When written specially to point out the causes of the changes, it is called the *Journal*: When the particular parts of each transaction, separate from each other in point of time, are collected together in the great book, the *Leger*. They also form a general history, but of a nature different from the two former.

The Grecian history has left us a memorial of great

anxiety about public accounts in Pericles, who was admonished by Alcibiades not to trouble himself about them; and in the person of Augustus, who presented the state of the nation (*Rationarium*, *Suet. in Aug.* c. 28.) to the magistrates and senate assembled in his own house to a committee of accounts.

The Grecian and Roman languages furnish also the names used in the arrangement: *Diploma*, a grant; *syngraphum*, a bill; *gramma*, a note; *cautio*, a note; *tabula*, the entire account; *magnus liber*, the *Leger*; *tempus venale*, the day of sale; *sanguinolentæ centesimæ*, — usury, (*Seneca, De Benef.* lib. vii. cap. 10.); and *utraque pagina*, debtor and creditor, (*Pliny*, lib. ii. cap. 7.)

The slaves formed a great part of the population of the Roman world; they were employed on the farms, and in the work-houses, which were manufactories; their maintenance, and rewards (*peculium*), were certainly valued by their labour; these farms extended nearly over entire provinces; these work-houses were as large as cities; and these slaves were as numerous as warlike nations (Seneca, *Ibid.*); and all these were under the controul, and for the advantage, of individuals in a private station, who diligently and eagerly examined the great book. (Seneca, *Ibid.*)

Notwithstanding this, there is no method by which it can be ascertained, whether their accounts were kept by a general history in the order of time, or by the particular history of each article, as those do now who are not acquainted with the art. No book, or part of a book of this kind, has been preserved during the revolution of the Roman world.

The cities of Italy in the middle ages raised themselves to power by commerce. In the time of the crusades, they were not only carriers, but also contractors. The Venetians felt the effects of the league of Cambray in the beginning of the 16th century. It was after this period that the system of book-keeping, the appendage of commerce, became known in England. Hugh Oldcastle published his work in 1543, and John Peile in 1569. These and their successors laboured only to settle the forms of words in the two Day-books, leaving the Leger without an absolute rule, (§28. 51.) Nothing more was done even on the continent. Mr Macolm at length published his work; wherein he shewed by example, that the writing of the titles of the Leger accounts in a margin of a third of the page to the left of the entry of the Waste-book, was a sufficient preparation for the Leger; because the original entry was in the view of the book-keeper: thus the full half of the former labour was saved. Mr Ephraim Chambers (edit. 1738) strongly recommended this practice; but few followed this good example. Even the most popular of the present writers, Mr Kelly, has not thought proper to recommend it.

Transferring the accounts from one book to another, and thus making three fair copies of the same transaction, one in the Journal, and two in the Leger, produced a great degree of weariness and inattention, and of course mistakes. The balancing of the Leger was a most serious undertaking, and seldom successfully accomplished; and even then, it could not be proved to be an exact transcript of the Day-books. To remedy this, Mr Jones of Bristol, an accountant by profession, in 1796, published a work, to shew a method of forming a balance-sheet in the Day-books. For this purpose he used a Day-book for the entries of personal and cash accounts, and another for the entries of goods, with their prices; but without any reference to the personal or cash accounts, but by the dates. The personal and cash accounts were respectively entered in the marginal columns; and their total were to be the same as the general column of entry, which was placed near the creditor marginal column. With this preparation he set out; and having collected the balances of goods, added the total to the debtor column of the cash and personal accounts, and truly prepared for the answer, according to the examples given. The proposal and book were received with an eagerness which manifested the anxiety of the mercantile world. Mr Jones failed, because he

did not understand the language of the art; because he did not know the only difference which exists between the two orders of accounts, of those which have inner columns and of those which have none; and because he did not observe how these two orders of accounts concur to form the balance-sheet in the Leger. The reviewers (*Analytical Review*, 1796, April) equally shewed their want of information on the subject, when they spent their time in refuting his phantom of single entry; and by asserting, that nothing was gained by the system if it were double entry. They did not observe the omission of all those accounts, which, by having inner columns, could not be introduced into his plan. A later writer has asserted, that the detection of an error decided the controversy. Mr Jones' examples could admit but a clerical error. The principle must hold; but Mr Jones' plan failed, because there could be no reference to the accounts of goods; because no entry could be made of those acquired by barter, nor of accounts between employers and factors, nor between dealers in exchange; and especially because he omitted the only difficulty which can occur in balancing a set of personal and cash accounts. This happens when the merchant lessens his debt by anticipated payment; for this an allowance is made to the merchant, which truly alters the correspondent creditor side of the account, (See Jan. 27.) and must be taken off by some title: discount is the one chosen in the following system. Two entries are made there, to explain the principle. The one for notes payable could only be introduced by the author in his original work.

At length a true and correct system of balance in the Day-books was published September 1809, in Dublin. The experiment of its utility was tried on a very popular work, known by the title of *The System of Italian Book-keeping*, by the Rev. Daniel Dowling. The trial shewed immediately the only error in the Leger of that work, which had crept in by the mistake of a pretender to the knowledge of the plan of double entry; and it also shewed two errors in the copy of that work published with the name of Mr Jackson, for which there could be no remedy but by single entry; which is out of the plan.

Thus the only point which remained to be attained to complete the system is now in existence; and an easy and true criterion is presented to the merchant, to enable him to prosecute his business without waiting for the tedious operation of distributing and closing the accounts in the Leger; and the book-keeper is consoled, by shewing, that his balances in the Leger are the same, part by part, with those in the Day-books. See *Balance-sheet*.

An index for the personal accounts, formed like the index of the letter-book, will enable the book-keeper to make out all personal accounts and bills of parcels, in a more easy manner than can be done while the Leger is kept in the abridged form in which it appears in the printed systems.

In houses of very extended business, it is necessary to have two or three Day-books, that the clerks of the sales may not be interrupted in making their entries by the interference of the book-keeper, as a

- Book A. for Monday and Thursday;
- Book B. for Tuesday and Friday;
- Book C. for Wednesday and Saturday.

CHAP. I.

Nature of Book-keeping.

1. Every transaction of mercantile business consists of two parts,—the giving of one thing for another. This giving away and receiving are two different relations, each of which requires its distinct entry, to shew the change of property; and thus,

2. Book-keeping is the art of keeping accounts by double entry.

3. It consists, *first*, In the method of recording the transactions in the several books; *secondly*,

4. In transferring the accounts from one book to another; and, in some, from a particular account to a general account; *thirdly*,

5. In the method of finally ending each account; commonly called, closing the account.

6. The whole of property is distributed into,

Money,	}	Debts due to the merchant, or by him.
Wares,		
Paper effects,		
Single effects,		
		Engagements.

7. And this entire property is generally expressed by the word, Stock; which means, fixed at the disposal of the owner, and liable to all claims on him.

8. The ordinary means of acquiring property being by barter or service, the word *transaction*, which expresses the giving away, is applied to all mercantile business, and the detail is as follows :

9. Receiving,	}	Money,
Paying,		
Lending,		
Borrowing,		
Lodging,		
Drawing,	}	Wares.
Buying,		
Selling,		
Bartering,		
Consigning,		
Receiving consignments of,		
Making or receiving,		
Abatements for defects in,		

10. Issuing,	}	Bills.
Accepting,		
Drawing,		
Remitting,		
Protcting,		
Paying protested bills, for the honour of the drawer.		
Receiving or paying bills, with discount.		

11. Issuing or receiving bonds.

Lending,	}	on bottomry, or
Borrowing,		

12. Buying,	}	Ships.
Selling,		
Freighting, or letting,		
to freight,		
Buying,	}	Houses and Lands.
Selling,		
Letting,		

13. Assigning,	}	Debts.	}	Active due to the mer-
Counterbalan-				chant.
cing,				Passive due by the mer-
Discounting,				chant.

14. Giving or receiving security for old debts.
 15. Making conditional bargains.
 Making or receiving presents.
 Finding or losing.

CHAP. II.

Principal and Auxiliary Books.

16. 1st, The Waste Book.
 2d, The Journal.
 3d, The Leger.

17. The Auxiliary Books are,

1st, The Cash Book.	}	8th, The Copy Book of Letters.
2d, The Bill Book.		9th, The Book of Postage of Letters.
3d, The Invoice Book.		10th, The Book of Ships Accounts.
4th, The Sales Book.		11th, The Receipt Book.
5th, The Book of Accounts-current.		12th, The Pocket Book of Memorandums.
6th, The Book of Commissions.		
7th, The Book of Charges.		

18. The Book of Accounts-current,
 The Book of Commissions,
 The Book of Charges,
 The Copy Book of Letters, and
 The Receipt Book,

are so useful, that they are introduced into every office.

19. The method of arrangement in the auxiliary books, depends on the rules in the principal books; therefore, the forms of these are the first to be explained.

CHAP. III.

The Waste-Book.

20. The Waste-book is a Day-book, in which the several transactions which occur are recorded in the order of business, and in the most plain language.

21. It begins with an inventory of the whole property of the merchant, authorised by his name.

The circumstances to be mentioned are,

1st, The date.
 2d, The part of the transaction that belongs to the merchant.
 3d, The person.
 4th The payment.
 5th, The quantity and quality, mark, &c.
 6th, The price.

22. It is ruled with three columns to the right, for *l. s. d.*; one to the left, for a margin; to which it is convenient to add another inner column, penciled and parallel to the margin, at the distance of four letters, to regulate the beginning of the lines, specifying the quantity and quality.

23. The entries are to be made on the left hand page throughout this book. Particular care is to be taken, that no space be left at the bottom of the page to introduce a new article; and that no article shall be inserted near the bottom of the page, unless it can be fully entered in it: otherwise, the space must be occupied by a diagonal line.

24. The date is in the centre, and ink lines are drawn from it to the perpendicular lines, in every transaction.

25.	January the 1st, 1807.				
	Bought of A. B for ready money, 40 pieces of linen cloth at 3 <i>l.</i> per piece	120	0	l.	s. d.
					0 0

CHAP. IV.

The Journal.

26. The Journal is a Day-book, in which the two parts of every transaction of the Waste-book are ascertained by their proper titles, and by their mutual relation of debtor and creditor in the transaction, to be brought to their separate accounts in the Leger.

Hitherto this was made a separate book, and was ruled in the form of the Waste-book.

27. In the present system, the right hand page of the Waste-book is divided into two equal spaces from the top to the bottom of the page, with money columns in each; and the titles belonging to each part of the transaction are written in a protracted horizontal line, with their corresponding expressions in the Waste entry, either in the column to the left, called the debtor column, or in the column to the right, called the creditor column, according to the nature of their relation to each other. Each division is to have a margin for a reference to the Leger, by a single figure, which points out the folios of the Leger, when these accounts have no entry in the Numero-book; but when they have, a fractional expression is used, and the numerator points to the Leger, and the denominator to the Numero-book. Each title is written in a large and thick letter.

28. By ascertaining the titles, and their relation to each other, the articles are sufficiently prepared for the Leger, and for the novel purpose of a balance by the Day-books. The narrative of the Journal entries become useless, because the original entry is in view on the left hand page; and because these entries, which are in five different forms, never can give one precise rule for the narrative of the Leger: They most commonly apply to the debtor entry, and but in one case to the creditor entry; whereas these two parts have always separate and distinct forms of narrative in the Leger, appropriate to their titles, except in the conjunction of some personal and real accounts; as will appear in the direction to be given for the narrative of the Leger; an instruction which has been omitted by the several writers on this subject.

29. The titles of the accounts are so well arranged, and so brief, that they not only express the object of the transaction, but also the relation in which it stands to the person who conducts it; thus, the titles are first divided into the classes of *real, personal, intermediate, or summary*; and, since these accounts may be for the sole benefit of the conductor, or for the benefit of another, or for himself and another, they are divided into

Proper Factorage Company	}	which are called	{	the first set; the second set; the third set.
--------------------------------	---	------------------	---	---

30. For the understanding of the relation which the parts of the transaction bear to each other, marked by the words debtor and creditor, it is necessary to observe, that the entry of the Waste-book is (according to the language of grammar) in the active form without any abbreviation, as I bought one hogshhead of sugar for ready money:

While the entries of the Journal and Leger are in

the passive form, accompanied with a considerable corruption of a word derived from the Latin language, and also an abbreviation.

31. The word debtor is corrupted from *debitur*, the passive form of the obsolete verb *debio*, to bind, agreeing with the title (Lennep, *Latin Etymology v. debio*) and in like manner creditor is corrupted from the compounded passive verb *creditur*: this is formed from *do*, —to give—and the participle *cretum* separated, as meal by a sieve, (Kuster, *v. Cerno*) this analysis is plainly proved by the English phrase connected with these Latin words; thus,

The thing received is bound to, or connected with the thing given for it in barter. One kind of wares is connected with another, or with the person who sold it in trust.

But the manner of the connection is to be supplied by the mind. In this sentence, the figs came from Turkey to London; the word *from* shews the beginning of the journey, and the word *to* marks its termination: the same word *to* must also be used to mark every part of the progress of the journey: as first to Malta, then to Gibraltar, to Falmouth, to London: in the same manner the word *to* in this art marks every person with whom (whether owner, factor, or partner factor,) and also every property with which the buyer, borrower, or broker, may be connected, from the commencement to the end of the mercantile transaction.

The expression is then: These wares stand me in ten pounds: that is, stand to me in the place of ten pounds given for them; the word *cost* being formed from the Latin verb *consto*, to stand with. The wares were connected with the ten pounds as a barter, before they were connected with me as the owner, or on the behalf of the owner. This shews the reason of the abbreviation of the Journal and Leger forms. The thing given for another is separated from its account, for the property and the cause of the separation is expressed and accompanied with the word *by*: to which, whenever it is used in the passive form, the mind must connect, either agent, instrument, or cause.

This word *by* is no other than the word *be* in the imperative mood; and *he cash* the cause, is of the same import, as *by cash*. See *Diversions of Purley*, vol. i. p. 402.

32. By this statement it will appear, that the words Debtor and Creditor have but one uniform meaning in the whole system, that is,

<i>Debitur</i> is bound to or connected with the thing given for it, or the person who gave it.	<i>Creditur</i> is separated from its account by the thing received, or the person released.
---	--

Connected with an error.	Separated by an error.
--------------------------	------------------------

Connected with a new account or folio, whether particular or general.	Separated by a new account or folio, whether particular or general.
---	---

33. The articles of real accounts, when connected with each other, shew instantly a barter, or exchange; personal accounts, when connected with each other, shew mutual claims and releases. Personal accounts, when connected with real accounts, shew claims or releases substituted for barter.

34. There are besides titles of accounts to record the general state of property.

1st, At the commencement of business, and also the receiving or giving away any property for any cause not connected with a real or personal account, service, or engagement.

2d, In its progress by service or engagement.

3d, The profit and loss arising from the purchase and sale of commodities in the respective and particular account of each article.

Although all these may be entered in one general account, titled Stock, merchants have commonly separated them into six, which have titles in the Journal and Leger.

35. There is as yet a seventh general account, called Balance, which has hitherto been peculiar to the Leger; but can be formed with more ease and certainty in the Day-books.

36. *The Journal Titles of Real Accounts which are to be kept in the Leger.*

Money.	Ready money and Bankers Notes.	Cash.	Proper.
		In the Merchant's possession for his own account.	Ware by name as Claret.
Wares.	Bought for exportation.	Linen cloth.	
		General account of wares.	P.
Wares.	Consigned to another for the Merchant's account.	Voyage to	P.
		Voyage from to	E. P.
		A. B. his account of wares.	Factorage.
		Claret in Co. with A. B. &c.	C. F.
Wares.	Consigned by a Factor to another for the Merchant's account.	Adventure in Co. with C. D. & Co	E. C.
		In the possession of the Merchant for the account of another.	
Paper Effects.	Under his direction for himself and others.	Bills and notes.	P.
		Under the direction of another for a joint account.	
		Bills or promissory notes payable to the Merchant.	Bills or notes payable.
		The Merchant's accept. or notes.	
Paper Effects.	Contracts for money lent to fit out ships, and payable on their safe arrival.	Bottomry.	P.
		Bonds for money lent.	Bonds.
Single Effects.	The Merchant's bonds.	Bonds payable.	P.
		Ships.	Ship (by name.)
		Houses and lands.	House and lands in the county of P.
	House furniture.	Moveables.	P.

37. *The Journal Titles of Personal Accounts*

1st, A common personal account.	A. B.	P.
2d, An account of the merchant's affairs done by another.	A. B. my account.	P. E.
3d, An account current of the affairs of another done by the merchant.	A. B. his account.	F.
4th, Do. for a joint account.	A. B. his account in Co.	C.
5th, Do. for a joint account of Exchange in Co.	A. B. our account of exchange in Co.	C.
6th, Do. do. with a factor.	A. B. our account for Co.	E. F. C.
7th, Several debtors for small sums.	General account receivable.	P.
8th, Several creditors for small sums.	General account payable.	P.

38. *The Journal Title of intermediate or summary Accounts are,*

1st, The state of the merchant's property at the commencement, or at the closing of accounts, and every increase or decrease of his property in the intervening time, without giving a valuable consideration of property for such increase, or without receiving a valuable consideration for such decrease	Stock.
2d, Gains or losses by business	Profit and loss.
3d, Expenses of business by house-keeping, servants, rent	Charges.
4th, Gain or loss by transacting business for another	Commission.
5th, Gain or loss by lending money.	Interest.
6th, Gain or loss by insuring for others	Insurance.

There is besides another Summary Account hitherto peculiar to the Leger.

1st, Balance the difference between the inner columns of the real accounts, and of the inner columns of the factor's accounts in foreign money, and also of factor's accounts of domestic money, attended with exchange, and the difference between the two sides of personal accounts, except the single case of insolvency.

39. For the ready management of those titles, the following rules have been contrived :

A Real Account is

<i>Dr.</i>	<i>and Cr.</i>
When it becomes mine, To the Thing, Person, Service, Engagement,	
The cause or occasion of this for its value, or its improvement.	When it ceases to be mine, By the Thing, Person, Service, Engagement;
	Which is the cause of this separation, and produced by it.

A personal Account is Dr. and Cr.

When he gets into my debt.	When he gets out of my debt.
For what he then contracts.	By what he pays or ceases to owe.
When I get out of his debt.	When I get into his debt.
To the Thing, Person, Service, Engagement,	By what he gives me.
The cause or occasion of it.	

A Summary Account.

When Dr. And connected with a real or personal account implies a loss.	When Cr. And connected with a real or personal account implies a gain.
--	--

There are also three Maxims.

FIRST MAXIM.

40. When the summary accounts are debtors, and thus the cause of the separation of some real or personal account, there is a loss : this is true ; but in a secondary consideration : the immediate value of the title, and not the form of the entry, proves the rule ; for if a personal account be insolvent, or wares be damaged, a loss is incurred as certainly as by any of the summary accounts.

SECOND MAXIM.

41. To take off a debit, credit the account *by* so much ; to take off a credit, debit the account *to* so much ; the relative value of either side is changed by the equivalent addition, and thus all erasure in the book is avoided.

THIRD MAXIM.

42. To carry a debit from one folio to another, make the former creditor and the latter debtor. To carry a credit from one folio to another, make the former debtor and the latter creditor. This maxim is but a consequence of the second, and the truth of both depends on the meaning of the words debtor and creditor.

CHAP. V.

The Leger.

43. The Leger is a book into which the several transactions which are dispersed in the Waste-book and auxiliary books, and prepared by the Journal entries of the titles, with the relation of debtor and creditor, are transferred each to its proper account.

44. By this arrangement, the merchant readily perceives by the inner columns the true state of each real account in respect to the quantity remaining, and by the inner columns of those personal accounts which have them, what he owes, or is due to him ; and by the outer columns of the other personal accounts, what is due to him, or what he owes ; and in respect to the summary accounts, the state of the property at the commencement, and any gain or loss not arising from business, service, or engagement.

45. But, to know the total state, another operation is necessary, called the Balancing of the Books, which is done by forming a balance sheet ; this has hitherto been confined to the Leger ; its nature, and check in the Leger, will be explained in Chap. VII. § 73.

46. The accounts in this book consist of two parts ; the two pages of the book, as it lies open, belong to the same account ; that to the left is called the Debtor side, that to the right the Creditor side.

47. The debtor side is opened by the title of the account, and the word debtor, and the creditor side, thus,

Claret, Dr. Contra, Cr.

48. The accounts are opened in it in the order in which they are in the Journal ; and are transferred to it by the direction to the marginal reference in the page of the Leger, in which the debtor and creditor titles respectively are, § 27.

49. This book has an alphabet for all the accounts : Each kind of wares is classed by its name ; each general title by its name ; and each person by the surname, with the Christian name annexed.

50. It is ruled with three columns to the right side of each page, and immediately to the left of these with a column of reference to the correspondent folio of the Leger.

And next are the inner columns respectively for
Marks,
Quantity,
Foreign money,
Domestic money attended with loss and gain.
The sum specified in bills and notes, and day of payment.

It is ruled on the left side of each page with a line, which, with the margin, leaves a space for the name of the month, and a line to leave a space for the day of the month.

To which it will be convenient to add another line for the Journal folio page in which the transaction was entered ; it is obvious, that the transactions of an extensive business may occupy several folios ; in any other case, the day of the month will answer.

51. The circumstances to be entered on the respective side of the two titles, when there is but one debtor and one creditor, or on the respective side of the titles, when there are several debtors and creditors.

52. On the left hand page, The Leger title of the account being entered, the following circumstances are to be observed in making the entry :	And on the right hand page the words, Contra, Cr. Being entered,
1st, The date ; 2d, The Journal folio ; 3d, Each creditor title, which is the cause of this entry ;*	1st, The date ; 2d, The Journal folio ; 3d, Each debtor title, which is the cause of this entry ;

4th, The transaction belonging to the title ; 5th, the mark, quality, &c.	4th, The transaction belonging to this Leger title ; 5th, The mark, quality, &c.
6th, The quantity, { or in some accounts inner columns for domestic or foreign money attended with loss or gain ;	6th, The quantity, { or in some accounts inner money columns for domestic or foreign money attended with loss or gain ;
7th, The folio of the creditor ; 8th, The amount in the money columns.	7th, The folio of the debtor ; 8th, The amount in the money columns.

* When several titles are united in one transaction, the word *Sundries* is used to include them. By this method it is impossible in the Leger to ascertain the correctness of the entry.

And therefore all the entries are formed in a different manner.

entries in it are very particular, as will appear from this example :

1810.	Cash.	Dr.	£	s.	d.
Aug. 25	5 To sundries, received from Connor	Bryan	6	96	0 0
But in this manner the full proof is in the Leger.					
July 25	5 To Laurence Lawson, H.I. Wares	} Received from Bryan Connor	6	50	0 0
	To Paul Leech, Rouen, H.I. Burgundy Wine,		6	46	0 0

1st, The number of the bill in the order of its entry ;
 2d, { The Drawer, Acceptor, Promiser ;
 3d, Promissee ;
 4th, Every Indorser ;
 5th, Date ;
 6th, Day payable ;
 7th, Amount of ;
 8th, Cost of ;
 9th, How disposed of ;
 10th, The amount received.
 The 8th and 10th columns are the exact drafts of the outer columns of the Leger entries.

59. The Invoice-book contains every particular relating to the goods shipped in the most obvious language ; as, goods shipped in such a ship, A. B. master, consigned to A. C. of such a place, to be sold for account, or by order of ; or for the account of E. F. and me ; or for the account of A. G. and E. F. and me, each $\frac{1}{3}$ d.

60. Then mention the Quantity, Quality, Mark, Number, Cost, Charges, and if the transaction be of another, the } Commission.

After every particular is mentioned, the total is carried to the waste entries, in which there ought to be a reference to the folio page of this book.

61. The Book of Sales is written in the form of the Leger, like the Invoice-book.

It contains on the left hand page the particulars of the wares to be sold, and on the right hand page the different sales made. Though in the form of the Leger, it is one of the Day-books, and may have all the advantage of the Leger reference ; thus, it may be a sure draft for the book-keeper. It was introduced into the office to shew immediately the quantity of wares for sale ; afterwards its great utility appeared by the opportunity it afforded to make up the factorage and company accounts, when it was not possible to do so on account of the great arrear in the posting of the Leger. The final entries of each account of this book are carried to the Journal, and then to the Leger ; in both they are posted by the title Sundries ; about which title, see note on § 52.

This book will be mentioned § 182 ; it is of principal use in forming the balance sheet, and, by the brief manner in which it is formed, will give no additional trouble in the office. See the Numero-book of each of these sets, immediately after the Journal, from which it is posted by the denominator of the fractional expression annexed to those accounts that are to be brought to it.

62. The Book of Commissions contains a fair copy of all the orders received from employers, by which the merchant must exactly regulate his conduct to avoid all loss through mistake on this part.

63. The Copy-book of Letters is also necessary for the same purpose.

64. The Book of Ship Accounts, like the Invoice-book, contains too many particulars to be left to the entry in the Waste-book.

The expenses from the arrival to the sailing should

CHAP. VI.

Auxiliary Books.

53. Having shewn how the transactions are entered in the Leger, the forms of which are followed in the Cash-book, in the Book of Accounts Current, and in the Book of Charges, some observations are to be made on them, as connected with the Leger.

54. In the Cash-book are entered on the left side the receipts, and on the right the disbursements,

- The Date,
- Consideration, *i. e.* debtor or creditor,
- Person,
- Specie,
- Sum.

Once in a month the total is transferred to the Waste-book, and through the Journal to the Leger.

It is better to post it immediately in the Leger, and check it by the folio reference to and from the Leger.

55. The Book of Accounts Current contains the copies of such accounts as are sent to employers : they are evidently in the Leger form, though more particular than the general entries of the Leger admit ; for the charges, which are collected into one sum in the Leger, may in the Journal post have several lines ; therefore an exact copy is necessary to prevent disputes. This book ought to have an alphabet as well as a Leger check. The Example, § 164, will shew how exactly these accounts should follow the accounts in the Leger.

56. The Book of Charges is useful to save the immense trouble of making three different entries for each trivial sum which must be expended in a large family connected with an extensive business. The use of the other auxiliary books is to be now explained.

57. The Bill-book. The immediate use of this book is to save the trouble of resorting to the Leger, to examine when the bills become due, and also when the merchant's notes become payable ; that the former may be collected, and provision made for the payment of the latter.

58. It may be advisable to enter in this book any sums which are otherwise receivable or payable within the succeeding month ; such as annuities, rent, &c. The

make but one Leger entry, which will shew the great importance of this book. It ought to have a Leger check.

CHAP. VII.

The Methods hitherto used to prove the Leger to be a Transcript of the Day-book and the Balance in the Leger.

65. It is taken for granted, that every transaction of the merchant's business is truly entered in the Day and Auxiliary books. Any omission in these must be supplied by memory, and regularly posted.

66. A great difficulty arises, to know whether the Leger be a fair and true copy of the Day-books, and to prove this various expedients have been contrived;

- 1st, Such as the examination of the posting marks in the Journal.
- 2d, The particular, and
- 3d, The general trial balance.
- 4th, The separation of the money columns by months in the Leger.

The utility of each of which shall be now examined.

67. When any article is posted from the Journal to the Leger, there is a mark by a figure, referring to the page in the Leger in which the same entry is made; each figure, according to its place, (§ 48.) expressing a debtor or creditor entry. To examine these, by calling over the whole Journal, gives a proof, by inspection, that each article is entered both on a debtor and creditor side.

68. The next process is, to add all the debtor columns of the Leger into one sum, and the creditor columns into another. If these two sums agree, there is nothing to hinder the merchant to proceed to a balance; if they do not agree, a trial balance is to be made of each month, that the particular month in error may be known.

69. For this purpose, it is better to have this done at the close of every month; that a general balance in the Leger may not be a matter of uneasiness to the merchant.

70. It may happen, that the credit or debit may be really entered, but in an account to which it does not belong. This error cannot be removed but by inspection; at the same time it must be observed, that this error may extend only to two or three accounts, and seldom to more than five. In the plan now presented to the public, this inconvenience is removed.

71. A method has been lately recommended, to form four money columns to the left of the debtor side, each to contain three months, at which period the total was to be entered in one line in the narrative of the account; the same process was to be observed in the right of the creditor side, and carried into the narrative of the creditor side. This seems to abridge the labour of the merchant, but has this evil consequent to it, that his accounts furnished can never be the transcript of his Leger, for the important entries of it, (§ 55, 56, 61.) should the Day-book be lost or injured, the memorial of the whole transaction is utterly destroyed; while, by the common method, these two inconveniences are avoided.

72. From what has been said, the total sums of the debtor and creditor side must be found equal, before the merchant can proceed to the final business of closing the accounts.

73. The word Balance has, to this period of the Book-keeping, been used to express the equality of the whole

of the opposite sides of the Leger entries; but now it is limited to point out the difference between the amount of the inner columns of all the real and personal accounts, and the difference of the outer columns of the cash account, and of such personal accounts as have no inner columns, (§ 38.) except the single case of insolvency.

74. Thus it is a title peculiar to the Leger, and is an account formed by

<i>Debtor</i>	<i>and Creditor.</i>
<i>On the debtor side are the</i>	<i>On the creditor side.</i>
Cash,	The debts due by the merchant.
Wares not sold,	The amount of sales of such goods as could not be specially valued.
Paper effects, } remain-	
Single effects, } ing.	
Debts due to the merchant.	
The cost and charges of such goods as could not be balanced, as their special value was not known.	

This leads to the solution of the problem of Book-keeping, *What is the merchant worth?* The difference between these two sides is evidently the answer; and the proof is given by the succeeding operation.

The difference between the columns of the cash account being found, it is brought to the balance sheet. The inner columns of the wares are compared, to shew what quantity remains; this is found and valued at the first cost, and the amount carried to the outer column, and from it to the balance title: next, the amount of the inner columns of the personal accounts is valued according to the rate of exchange, and carried to the outer column, and from it to the balance sheet; and, finally, the difference of each other personal account is carried to the balance sheet. What had been done on the opposite sides of the whole Leger is now to be done on each particular account; and the difference between the two sides being added to the less, the equality of the two sides appears instantly to the eye. In pursuance of this plan, the outer columns of all those accounts that have inner columns, and the inequality of the sides of the summary titles of

Charges,	}	are to be made equal, and the title chosen for this is, Profit and Loss.
Commission, and		
Interest,		

Profit, means excess; loss, separation; so in those accounts which have inner columns, if the debtor side exceeds the creditor, there is a loss; because the produce of the sale was less than the price of the purchase: on the contrary, if the creditor side exceeds the debtor side, there is a gain, which remains unnoticed in some real or personal account. From this it must appear, that this summary account, profit and loss, is appropriated to the Leger, and can never appear in the Journal, unless some entire account be at that time closed in the Leger, as will be proved in the process of the second and third sets; it must also appear, that this title profit and loss is unnecessary in forming the balance sheet, when that account is not connected with the Leger. The particular sums connected in the several accounts, with the title profit and loss, are transferred to one general account, and the difference of the two sides of it made equal by the title stock. If the difference is to be

brought to the creditor side of the stock account, it shews, by addition, what is the property of the merchant; and if the difference is to be brought to the debtor side of the stock account, it shews, by subtraction, what is the property of the merchant; and, therefore, these two accounts are necessary to shew, that the balance in the Leger is correctly taken; and is the only proof that can be given, that errors have not been committed in the posting of the Leger.

75. Now, in the balance sheet, the difference between

<i>Dr.</i>		<i>Cr.</i>
And what the merchant has, and	What the merchant owes.	
What is due to him.	Is really what he is worth.	

And in the stock account the difference between

<i>Dr.</i>		<i>Cr.</i>
Or lost since.	What the merchant had when he began.	
	What he gained since.	
	Is really what he is worth.	

Therefore these two accounts, apparently different from each other, leave a proof, that the accounts are fairly stated, so far as they relate to the Leger.

The entire value of the property at the commencement was represented by the stock account; the increase or decrease of it was particularly marked by the closing of the real accounts, of the personal accounts with inner columns, and of the three summary accounts, and brought to the stock account.

The property in the actual possession of the merchant, or under his claim, can be nothing more or less than the substitute of stock, increased or decreased by the profit and loss account.

CHAP. VIII.

The Method of Closing the Accounts.

80. Some accounts are closed without any additional entry, when the inner and outer columns are respectively equal.

81. Some are closed by balance, when the inner columns are not equal.

82. Some are closed by balance and profit and loss.

83. Some real accounts are closed by personal, either totally as factorage real, by employer his account; or partially, as company accounts, by the partner's account, and profit and loss.

84. Profit and loss, and balance by stock.

85. And stock by balance.

86. Therefore, all the other accounts are closed in the order of the pages of the Leger.

87. Then the balances are collected, and all the accounts, which of their own nature produce a gain or loss, are closed by profit and loss. It is closed by stock; and stock and balance close each other.

CHAP. IX.

The Titles closed by Balance.

88. The following titles are closed by balance :

Cash remaining.

Wares not sold.

Voyages: the account of sales not received.

Stock in a company not sold.

Bottomry, no account of the safe arrival received

Bills, } not received.

Bonds, }

Ships, or shares, } remaining.

Houses, lands, moveables, }

Personal accounts, when the total or part only is due.

CHAP. X.

Particular Methods for each Title.

89. Some are closed by balance and profit and loss, which shall be now shewn under each title.

Cash.

90. The debit shows the sums received, and the credit shows the sums paid; credit the account by balance for the excess of the debit above the credit, which is the sum remaining in the chest; if it should happen that the ready money in the chest does not agree with the sum mentioned, there is an error, which must be sought after, if considerable, and if it cannot be discovered,

91. And the cash be more than the balance account states, debit the account to profit and loss for the difference.

92. If the money be less, credit the account by profit and loss for the difference,

93. And then credit the account by balance for the exact sum in the chest.

Wares.

94. The debit shews the cost and charges and compensation for defects, and the credit the produce by sale.

95. There are four cases.

96. If none be sold, credit the account by balance for the amount of the debtor side.

97. If all be sold, debit the account to profit and loss for the gain.

98. Or credit the account by profit and loss for the loss.

99. If part be sold and part be unsold, credit the account by balance for what remains unsold, at its value, including prime cost and all charges, and then debit the account to profit and loss for the gain, or credit the account by profit and loss for the loss.

100. If it be difficult to ascertain the value of what remains unsold, the account may be closed by entering on the creditor side, thus, by balance for the total of the debtor side, and debiting the account to balance for the total of the credit side, by which the account will appear in the next Leger in the very state in which it was in the present Leger.

101. Leakage may happen in casks of liquor.

102. And a lackage in the weights or measure, (see also § 142. A. B. my account), which, when observed, ought to be entered and carried to the credit side of the respective account in the Leger, observing to begin the entry with a black line, and only to enter the quantity missing in the inner columns.

Goods bought for Exportation.

103. The debit shows the cost, and the credit shows when and to whom consigned; if all remain, close the account by balance.

104. And if but part remain, it is better to close the account with a double balance.

Voyage.

105. The debit shows the cost and charges of the cargo; the credit shows the neat proceeds as they appear by the amount of the bill of sales received from the factor.

106. If the account of sales be not received, credit the account by balance for the total of the debtor side.

107. If the account of sales be received, credit the account by the factor, my account; and for the difference remaining between the two sides, close the account by profit and loss.

108. If any return in wares or bills for the neat proceeds be received, credit the account by that particular title, and close the account by profit and loss.

109. If it be a general account of voyages, credit the account by balance for such as remain uncertain, and close the account by profit and loss for the remaining difference.

Bills.

110. The debit shows the cost of such as are received by the merchant, the credit shows what they produce.

111. Credit the account by balance for so many as remain, allowing a separate line for each bill, in the manner each is expressed on the debtor side.

112. For the remaining difference, close the account by profit and loss.

Acceptances and Notes Payable.

113. The debit shows the cost of those you have paid.

114. And the credit shows the consideration for which they were accepted or passed.

115. For the notes not yet paid, debit the account to balance in as many lines as there are acceptances or notes remaining unpaid, in the manner each is expressed on the creditor side, and for the remaining difference close the account by profit and loss.

Bottomry.

116. The debit shows what consideration was given for such contracts, the credit shows what they have produced.

117. Credit the account in so many lines as there are contracts remaining in the terms in which they are expressed on the debtor side.

118. Close the account for the remaining difference by profit and loss.

Bonds.

119. This is of the same nature as the last, and closed in the same manner.

Bonds Payable.

120. This is of the same nature as acceptances and notes payable, and closed in the same manner.

121. Houses, Lands, Moveables, } are of the same nature, and closed in the same manner.

A Personal Account.

122. The debit shows the merchant's charge against that person, the credit shows his charge against the merchant.

123. Debit the account to balance, if the creditor side be greater.

124. Credit the account by balance, if the debtor side be greater.

An Account Current of

125. The merchant's business done by a factor, and titled A. B. my account.

126. The debit shows the employer's charge on the factor.

127. The credit shows the factor's charge against the employer, so when the account is sent to the employer.

128. The particulars of the debit of the one must be compared with the credit of the other.

There are three Cases,

129. When the factor's money is of the same value and denomination, and drafts on them, or remittances to them are made at par.

130. When the money is not foreign, and drafts and remittances are not made at par.

131. When the money is foreign, and drafts and remittances are not made at par.

132. In the first case the account is closed like a personal account.

133. In the second case the account requires inner columns, for the particulars of which the factor and the employer account with each other; the outer columns shew, what the several particulars of the inner columns respectively produce.

134. The inner columns are closed by balance; which balance is valued at the current rate of exchange, and carried to the outer columns.

135. The outer columns are closed by profit and loss.

136. The third case requires inner columns for the factor's money; close the inner columns with balance for what remains due either to him or by him.

137. Enter the value in the outer columns at the current rate of exchange.

138. Close the account with profit and loss.

139. Note.—When a factor furnishes an account, it is to be compared with the employer's Leger account; the debtor of each, with the creditor side of the other, and the factor's columns with the employer's inner columns.

140. The additional charges are to be examined, that if there be any mistake, the factor may be advised of it without delay.

141. When every charge is found to be exact, enter in one line on the credit side of your Leger account, and in the inner columns the total; and unless it so happen that the account have no inner columns,

142. Make no entry for any charges of interest, brokerage, or commission in the outer columns, as was observed of leakage and lackage. § 101, 102; the only exception to this is, when the gain or loss may arise from different causes, as 1st set, Leger, folio 4, by interest, and by the exchange.

143. Close the account with profit and loss.

144. Note also, that it may frequently happen that the merchant may desire to examine his books without settling with his factor, in which case the true method is to close with a double balance as mentioned. To understand the examples given in the different sets, it will be useful to refer to the following Tables of the par of exchange, which were then published,

and this comparison will shew the course of the exchange.

145. A certain space of time allowed to the drawer of a bill, to give notice of the transaction to the acceptor, is expressed in the bill by the word *usage* (custom); it is a space of one or more calendar months, or months of 30 days; the first day of which, in some places, is reckoned as one.

The Days of Grace are a respite of Payment allowed.

A. B. his Account Wares.

[The particular name of each kind is expressed.]

146. The debit side shews in the inner columns the Mark, Quantity, Measure.

147. And in the narrative the debit expresses the charges attending the wares, by the title, by which these charges were defrayed.

148. The credit shews the produce of them by sale.

149. If the sales be finished, debit the account to all the charges not yet posted.

150. To Brokerage, }
 Cellarage, }
 Commission, }
 To the purchaser for any defect, and for the abatement made to the purchaser if he become insolvent, and the debt be not insured; if the sales be closed, the employer's account current is to be debited for these defects, and consequent abatement and losses.

151. To the employer (by his name) his account for the neat proceeds.

152. These are found by deducting the total charges from the total sales.

153. But if the sales be not finished, it is better to close this account by a double balance, § 100.

A. B. his Account.

154. The debit shews what the factor has advanced.

155. And the credit shews what the factor has received for the employer's account.

156. When an account current is to be furnished to an employer,

157. It is to be debited in so many lines.

158. To agio for the interest of the money advanced.

159. To commission for the trouble of receiving or paying money, at 10s. per cent. on the greater sum of the debtor and creditor sides, but not on both: those articles are not to be taken into this account that have commission charged on them, as is stated in the next paragraph.

160. To commission for the purchase of wares, at 2l. 10s. per cent.

161. To brokerage for negotiating the remittances of the factor, and any drafts of the factor for the employer's account, and also any remittances of the employer which are to be negotiated; these articles are taken from both sides of the account.

162. To postage, for all charges of this kind, to the day on which the account is furnished.

163. Close the account with balance due to the employer, or factor.

164. Or in case the account is not to be furnished, close it with a double balance, § 100.

Let the Learner consider the following Example of an Employer's Account Current, in the form in which it is to be sent to him, without the corresponding Drs. and Crs. of the Leger Account, with which it is connected.

9s. 1 $\frac{1}{2}$ d.

The direction of the Rules is to reduce the decimals to diverse denominations.

Wares in Company.

- 165. In the agent partner's Leger,
- 166. The debit shews,
The cost of the agent partner's share.
The total quantity.
The total charges.
All abatements.
The share of the neat proceeds belonging to each partner.

167. The neat proceeds are found by subtracting the sum of the charges and abatements from the total sales.

168. The remaining difference between the two sides is to be charged to profit and loss.

169. The credit shews the total sales, and the inner columns shew any deficiency by leakage or lackage; which circumstances are necessary to be entered in the inner columns, as it was observed § 102.

170. If the sales be not finished, it is more advisable to close the account with a double balance, § 100.

Adventure in Company.

171. This is arranged in the same manner as wares or voyages.

An Account with a Factor.

- 172. For a company under your direction.
- 173. The debit shews the employers' share of the first cost.
The whole quantity.
All charges and abatements.
The partners' share of the neat proceed, found as mentioned § 167.

174. The remaining difference shews the profit and loss.

175. The credit shews the total sales, and any defect by leakage or lackage, as mentioned § 102. This account is titled, Voyage from — to —, in Co. with C. D. and E. F. each $\frac{1}{3}$ d. and A. B. for Co. O/A.

A. B. Our Account of Exchange in Co.

176. Close the inner columns with balance, carrying the value to the outer columns at the current rate of exchange.

177. Then debit the account to the partners' share of the neat gain.

178. And close the account with profit and loss.

CHAP. XI.

The Balance Sheet in the Day-books.

179. The Waste-book is written as directed § 21, 22, 23, 24. on the right hand page; and the Journal on the left hand page, as directed § 27. The titles alone are written § 28, and they are so full, that they include every transaction, § 29.

180. This Journal is to be arranged so that every article, which must appear on the debtor side of the balance sheet, must appear without any confusion on the debtor side of this book; and likewise every article of the creditor side of the balance sheet must appear on the creditor side of this book. In all accounts called real, except

Cash,
Bonds,
Notes,
Acceptances, } payable,
Bottomry,

the creditor side should be the greater to reward the merchant for his time and trouble, and to improve his capital.

181. All accounts commence
By gift, } of { Money or Wares,
Barter, or }
Credit, }

and are disposed of in the same manner, or they remain with the merchant.

182. If they are sold or bought for cash, or on credit, their value appears on the debtor or on the creditor side of the Journal in the cash entry, or in the entry of some personal account; or if they are acquired by gift or barter, the quantity, quality, and value, are ascertain-

ed in a short account, (§ 58.) to which the merchant may with ease at any time resort, to ascertain what remain.

This short account is in

183. The Sales-book, or Numero or Warehouse-book. It is formed by debtor and creditor, and ruled in the manner of the Leger, with a column of reference to the Journal page of the entry.

184. It is uniformly posted by single entry, (because the counterpart is in the Journal,) except in the cases of

1st, Barter,

2d, Partial returns for consignments,

3d, And counterbalancing accounts between foreign factors. In these the two entries are in the Numero-book, 1st set, January 15th.

185. Wares received by gift are entered in the Numero-book; and if disposed of in the same manner, the quantity is separated by the creditor entry.

186. If the wares be bartered, the quantity given away is entered on the creditor side of its title, and the wares received are entered on the debtor side of its proper title.

187. The accounts with foreign or other factors, whose remittances are attended with loss or gain by exchange, have inner columns, which form these particular accounts in the same manner as the accounts of goods and wares; and, therefore, these balances, (§ 73.) are ascertained and collected in the same manner like the other balances, and respectively brought to the debtor or creditor column of the balances of the Day-book, according to the rate of exchange of the day, § 136.

188. All the accounts of wares, and with foreign and other factors, bills, and voyages, are entered in a very short though satisfactory manner, to enable the book-keeper to collect the balances, § 61.

189. The accounts of goods admit but of one exception, that is, when the precise value of any specific quantity cannot be made out, (§ 100.) in which case they are to be closed with a double balance, and the amount of the money, value of each sale, is to be entered in the Numero-book.

CHAP. XII.

Articles which have Entries in the Money Columns of the Journal.

190. The rule of posting the Journal is, the title being entered in the language of the Journal, enter the amount of each debtor and creditor entry in the money column.

1st, Of cash.

2d, Acceptances and notes payable.

3d, Bonds payable.

4th, Contracts for money borrowed on bottomry payable.

5th, The discount of the 2d, 3d, and 4th articles, in the event of payment before they become due.

6th, The accounts title, A. B. his account, A. B. C. their account.

7th, All common personal accounts; the debtor and creditor sides of all these accounts exactly agree with the debtor and creditor side of the cash and personal accounts in the balance sheet.

191. The creditor side of cash can never be greater than the debtor side, but by an error, § 89; if the creditor side of A. B. his account, and of A. B. C. their account, be greater, the merchant owes so much; and his property on the debtor side is lessened by so much.

192. But, Notes payable,

Acceptances,

Bonds payable,

Contracts for bottomry payable,

are real debts in their first entry, and being payable at a future day, may be lessened by discount; for this reason this title is to have a special entry in the money column of the debtor side, precisely to take off an error which would really be on the creditor side of the account; for example, if the note passed for 50*l.* be paid by 49*l.*; the article for which it was passed really cost but 49*l.* (See 1st set, March 19.) This item of discount will appear in the closing of these accounts in the Leger, by the title of profit and loss. All anticipated payments are within this rule.

193. Then let each page of the Journal be added, and the total of it carried to the balance sheet, and collected into one sum in the balance sheet.

194. The merchant then proceeds to examine by his Numero-book what

Wares,	}	Remain.
Bills,		
Bonds,		
Bottomry contracts receivable,		
Ships,		
Houses,		
Lands,		
Furniture,		

What is the original value of the goods closed by a double balance; the total charges of wares on commission not closed; his share of wares in company; charges on do; adventures in Co.; the balances due by foreign or other factors, whose accounts have inner columns; this total, with the total of the debtor side of the Journal, is the same that should appear on the debtor side of the balance sheet in the Leger.

195. And the total of the creditor side of the Journal, with the balances due by the merchant to foreign or other factors, whose accounts have inner columns, and the total cash amount of the sales of such wares as are closed by a double balance, and sales on commission not closed, form the same amount that should appear on the creditor side of the balance sheet in the Leger.

196. The difference between these two sides is the real property of the merchant, and solves the question, *What is the merchant worth?*

197. If the merchant desire to ascertain precisely his gain or loss for any particular period, he is then to debit and credit the stock title in the money columns in the Journal, whenever that title occurs, Leger, page 6.

198. And the difference of the two sides of the Journal, together with the balances of the Numero-book, will shew the gain or loss (balance sheet, Leger); for the credit side of stock countervails all the effects the merchant has, and the debts due to him; as the debtor side countervails all the debts he owes; and therefore, if the debtor side of the Journal, with the balances of the Numero-book, be greater, there must be a gain: if it be less, there must be a loss. In the same manner, if the amount of the debtor and creditor sides of the stock account be added to the balance sheet, (as it is, 2d account, Leger, page 6.) the gain or loss will appear in

the same manner. The stock account also may be formed from the balance sheet, as it is in the 3d account Leger Balance.

199. Finally, to prove the correctness of the balance sheet formed in the Day-books, there is nothing necessary, but to shew that the difference of the totals of the two sides of the Journal account is, and ought to be the same, as the sum or the balance of the cash and personal accounts in the balance sheet of the Leger. In the Leger, 2d account, the sum is the same; and all the other items are proved by inspection to be the same.

INDEX to the Day-Book.

BOOM. See **NAVAL TACTICS**, and **SHIPBUILDING**.

BOORS, a general appellation for the Russian peasantry, who are divided into two great classes, distinguished by the names of vassal boors and free boors. It is necessary to observe, however, that the free peasants, though generally comprehended among the boors, both in state papers, and in the enumeration of the people, are, in reality, a distinct class, forming a middle link between the burghers and the vassal peasantry, to whom the name of boors properly belongs. These free peasants cannot be alienated or sold; most of them possess immovable property, and are left in the undisturbed possession of what they earn, provided they duly pay their taxes, or perform their stated tasks of labour; they have the privilege of educating their children as they please; and, in short, are as completely exempted as their superiors from all authority, except that of the sovereign and the laws of the state. Under this class are included the foreign colonists who have settled in Russia as husbandmen; and the *odnodvortzi*, or one-house owners, who possess their houses and the lands belonging to them as free property, for which they neither perform feudal services, nor give any portion of their produce; but are compelled to furnish recruits, to pay the poll tax, and *abrock*, and are expressly prohibited from purchasing in villages, or possessing vassals as property. The *Kozacks*, or *Cossacks*, in all their branches, *Tartars*, *Bashkirs*, *Vogulls*, *Kalmucks*, most of the *Monadic* tribes, and the inhabitants of the steppes, as they have a real and heritable property in their lands, belong properly to the class of free peasants. Disbanded soldiers, who go to reside in the country, and vassals who have purchased their freedom from their superiors, or obtained it as a reward for their faithful services, are likewise to be numbered in the same class. The male Russian peasantry, or those of Little Russia, hold a kind of intermediate rank between the vassal boors and those we have described, being neither so dependent as the former, nor so free as the latter: they are attached as fixed property to the land, separately from which they can neither be alienated nor sold.

The vassal boors are sunk in the most abject slavery. Disqualified from holding any possessions of their own, they and their families are at the absolute disposal of their lords, by whom they may be alienated, sold, or exchanged, like any other part of their property. These degraded people may be distributed into three classes, — crown boors, boors of the mines, and private boors.

In the condition of the first class, who are the vassals of the crown, there are various gradations of servitude and misery. Some of them are absolute and disposable property; others are attached to the mines, and can neither be sold, nor have it in their power to remove; while others are merely tasked with a certain portion of work, or obliged to pay a stated quantity of the produce of their labours. A striking difference may be observed between the condition of the peasants of the crown, and that of the boors who belong to individuals. In general the former merely pay to government an *abrock* or rent of about five rubles at an average; and as they are certain that it will never be raised, they have every encouragement to exert themselves for the improvement of their fields, or the amelioration of their condition. Many of these are in such comfortable circumstances, that they might almost forget their state

of vassalage, did not the crown possess, and sometimes exert, the power of granting them away.

The crown boors are distinguished by various denominations, according to their respective employments, or to particular circumstances in their condition. Eight distinct kinds of crown boors are mentioned in the laws and ukases of Russia: empire boors, who belong neither to the court, nor the nobility, nor to the monasteries, but are members or burghers of the empire; imperial boors, who belong to the monarch personally, or rather to the court; boors of the black plough, who inhabit great part of northern Russia, as far as Archangel; post boors, who in lieu of the *abrock* and other taxes, are bound to keep post horses; court boors, whose service and tribute go to the support of the imperial court; monastery boors formerly attached to the monasteries, but now throughout Great, Little, and White Russia, uniformly found under the *Kameral-hofs*; economy boors, who, in Great Russia, were taken from the monasteries and churches, and made subordinate to a particular college of economy, established for that purpose, but since abolished, so that the boors are under the *Kameral-hofs*, retaining however their former name; and peltry tribute paying boors, who deliver their tribute in peltry or furs. The crown boors possess one important advantage over boors of every other description, being permitted to purchase from noblemen, villages, and lands, with the vassals belonging to them.

The next general class of boors are those called mine boors, who are attached to particular mines, apart from which they cannot be sold or exchanged, though they may be transferred along with the works to different masters.

The third class comprehends those boors who belong to individual noblemen, and whose condition, of course, depends entirely on the temper or the caprice of their lords. The condition of many of these boors indeed is far from being unhappy; for when their lords are wealthy and good natured, requiring only a moderate *abrock*, they are enabled to grow rich, and to enjoy many of the comforts of life. In general, however, the *abrock* demanded by their proprietors is regulated by their means of getting money, and becomes thus a direct tax upon the industry of the peasant. The *abrock* exacted by individual proprietors from their peasantry, amounts, at an average, to about eight or ten rubles annually for every male. Besides this *abrock*, the lord may demand from his slave the labour of three days during each week; or may even employ him every day, provided he furnish him with food and clothing. Nor is this task service imposed on male slaves alone. Women, and children above the age of ten, are likewise compelled to perform their share. When the peasant is thus obliged to give his labour for three days in the week, the *abrock* is in general diminished. But still both the quantity of labour which he has to perform, and the amount of the tax which he must pay, depends entirely on the will of his tyrant. To render his servitude still more oppressive, he must resign to his lord a tythe of all the property which he may earn by the culture of his little spot of land, or by any manual employment; and if by any accident he should be deprived of the tribute which he is expected to pay, he must beg, borrow, or steal, to make up the deficiency. The master is obliged to furnish his vassal with a house, and a small portion of land, the allotment of which is

settled by the storasta, (elder of the village,) and a meeting of the peasants themselves. If they happen to exercise any trade more profitable than agricultural employments, the abrock imposed upon them is proportionally higher. Peasants, employed as drivers, pay a certain portion even of their drink money, for being permitted to drive. The aged and infirm are allowed a certain portion of food and raiment; but if any of them choose rather to depend on public charity, than to subsist on the wretched pittance which they receive from their lords, they must pay a certain abrock out of what they earn by begging. A master is allowed to correct his slave by blows and confinement; but for any wanton cruelty is amenable to the laws, which are said to be executed in such cases with the strictest impartiality. A certain countess was lately confined in one of the prisons near Moscow with an unrelenting severity, which she had justly merited by her barbarity towards her slaves. Instances of the most dreadful cruelty, however, frequently occur. M. Heber, as quoted by Dr Clarke, mentions one instance of a nobleman having caused his slave to be nailed to a cross. The master was sent to a monastery, and the business was hushed over. The slaves, in their turn, are extremely vindictive. Some years ago, the master of a distillery suddenly disappeared, and it was universally understood that his boors had thrown him into a boiling vat. No slave can quit his village, or his master's family, without a passport, which he must produce to the storasta of every town or village through which he happens to pass. The punishment of a runaway is imprisonment and hard labour in the government workhouse; and if a person be found dead without a passport, his body is given for dissection. The boors on the coasts or frontier provinces often find means to effect their escape. In the interior it is extremely difficult, yet desertion is very frequent, particularly in summer, or when there is to be a new levy of soldiers. A slave can, on no pretence, be sold out of Russia, and in Russia to none but a person of noble birth; and if not noble, having at least the rank of lieutenant-colonel. This law, however, is sometimes evaded: Many of the boors are sold to plebeians; and all nobles have the privilege of letting out their slaves for hire. In short, the condition of the boors is, in general, deplorably wretched. The only property which their lords allow them to possess, is the food which they themselves cannot, or will not eat, the bark of trees, chaff, and other refuse; grass, water, and fish oil. If by any means they acquire any portion of wealth, it becomes a very dangerous possession, and when discovered, is invariably seized by their tyrannical lords. A peasant in the village of Celo-Molody, near Moscow, who had accumulated considerable wealth, wishing to marry his daughter to a tradesman of the city, offered his lord fifteen thousand rubles for her liberty. The tyrant took the ransom, and then told the father, that both the girl and the money were his property, and that she must still continue among the number of his slaves. "It is thus," says Dr Clarke, "we behold the subjects of a vast empire stripped of all they possess, and existing in the most abject servitude; victims of tyranny and torture, of sorrow and poverty, of sickness and famine." "Traversing the provinces south of Muscovy," he continues, "the land appears as the garden of Eden, a fine soil, covered with corn, and apparently smiling in

plenty. Enter the cottage of the poor labourer, surrounded by all these riches, and you find him aying of hunger, or pining from bad food, and in want of the common necessaries of life. Extensive pastures, covered with cattle, afford no milk to him. In autumn, the harvest-field yields no bread for his children. The lord claims all the produce. Can there be a more affecting sight than a Russian family, having got in an abundant harvest, in want of the common stores to supply and support them, through the rigours of their long and inclement winter!"

The empress Catherine often expressed her anxiety to abolish the system of vassalage throughout the empire, or at least to ameliorate the condition of the boors, and to restrain the abuses to which they were exposed. To accomplish this benevolent purpose, she instituted a regular tribunal for the boors, entirely chosen out of their own body; delivered the boors at the mines from the oppressive servitude in which they had formerly been held; appointed overseers and guardians to prevent every species of violence; and on all occasions recommended gentleness and humanity, of which she herself exhibited a most laudable example.

By far the greater number of vassals in Russia are those who have been born of bondmen. By the common law of Livonia, every child, born of an unmarried vassal, belongs to the estate on which it is born, whether the father has been bondman or free. Peter I., however, ordained, that a child born in such circumstances should be free, if a freeman own himself its father, and cause it to be baptized in his name. Notwithstanding the degraded state in which the boors are generally held, some of them rise to considerable respectability. Several have been known to obtain commissions in the army for their good behaviour; and others live comfortably at home, having abundance of wholesome food, and neat and becoming apparel. In some villages they display a degree of comfort, and even of wealth, which the peasantry of very few countries can rival.

A Russian nobleman estimates the value of his estate by the number of his vassals, as a West Indian estimates his by the number of hogsheads. Some of them possess seventy, or even an hundred thousand. In all mortgages, the national lombard takes the vassal at forty rubles; but in the sale of an estate, they are seldom or never estimated at so low a price. In the government of St Petersburg, every slave is valued at 200 or 300 rubles, according to the quality of the estate; in other parts of the empire their price is commonly much lower, though there is scarcely any part of the empire where it is under 100 rubles.

According to an enumeration of male inhabitants made from 1781 to 1783, in the forty-one viceroyalties of the empire, the number of crown boors was 4,674,603, and of private boors 6,678,239. See Tooke's *View of the Russian Empire*; and Clarke's *Travels*, chap. 9. (k)

BOOSHOOANAS, or BOOSHUANAS, a tribe of Caffres who inhabit a fertile country in the south of Africa. Their manners are remarkably simple, and their principal occupation is in attending their cows, and hunting the antelope. The relative duties of the men and women are, in a singular manner, interchanged. The women break up the ground with an iron hoe, sow the seed, reap the grain, and deposit it in their granaries in a state

fit for use; while the men attend the cattle, milk the cows, and prepare the different articles of dress for their wives and children.

The capital of the Booshoonas is Leetakoo, a large and populous town, which is divided into two parts by a river of considerable size. Leetakoo was estimated by the commissioners who visited it in 1801, to be as large in circumference as Cape Town, including all the gardens of Table Valley. The streets are regular, and the buildings very low. The ground plan of every house is exactly circular, and is from 12 to 15 feet in diameter. The floor consists of hard beaten clay, elevated about four inches above the surface of the ground. The lower part of the house, to the height of four feet from the floor, is formed of stone laid on clay, having wooden spars erected at certain distances. About one-fourth part of the circle is entirely open, and this open part was the part which seemed always to face the east. By means of an inner circular wall passing through the centre of the house, and of the same radius as the outer wall, so as to cut off one-third of the circumference, an apartment is formed, in which they deposit their clothing, their ivory ornaments, their hassagais, (the weapon which they use in hunting and fighting,) their knives, and other articles of value. In this apartment the heads of the family sleep, while the children sleep in the half closed viranda, which comprehends two-thirds of the circumference of the circle. The roofs of the houses are round, and pointed in the form of a tent, thatched with reeds, or the straws of the holcus. Every house is surrounded with a pallisade, the open space between which and the house is reserved for the granary. The grain is lodged in jars of baked clay, each of which holds about 100 gallons. Each jar stands upon a tripod of baked clay, which raises it about nine inches from the ground. A round straw roof, erected on poles, forms a covering for the jars in such a manner, as to allow an opening into each of them. Leetakoo contains about two or three thousand houses, and ten or fifteen thousand inhabitants. East Long 27°, and South Lat. 26° 30'. See Barrow's *Voyage to Cochinchina*, p. 390. (H)

BOOTAN, or BUTAAN, a province dependant on Thibet, and situated between that country and Bengal. The limits of this province are not accurately ascertained. Paridrong, and the chain of mountains near it, were supposed to have been the boundary between Bengal and Thibet; but it appears from later authorities, that they form the boundary between Thibet and Bootan. This country abounds with lofty mountains, covered with eternal verdure. Rich orchards, fertile fields, and thriving villages, crown their summits, while forests of lofty trees rise at their base. Bootan is bounded on the south, by a ridge of mountains, which, in the space of fifteen miles, rise to the perpendicular height of one mile and a half from the plains of Bengal. The few passes that are to be found in this chain are strongly fortified, and the road to Tassasudon, the capital of Bootan, is over the rugged summits of high mountains and dangerous precipices. In advancing still farther into the interior, we meet with another lofty chain of mountains covered with snow, called *Rimola*, or *Himaleh*, which is seen at the distance of 150 miles. This chain runs between Tassasudon and Paridrong, and the mountains are supposed to exceed in height even the highest of the Andes. Mr Turner is of opinion, that iron, and a small portion of copper, are the only metals in this

VOL. III. PART II.

province. The inhabitants of Bootan are supposed to have a nearer affinity to the Chinese than to the Hindoos. They carry on a considerable commerce with the people of Sirinagur. They bring to that country rock salt and borax, and carry back in exchange the salt which is brought from Lahore, and is called *Nemuk Lahoree*. For a more complete account of this province, see Turner's *Account of an Embassy to the Court of the Teshoo Lama in Thibet*. See also captain Thomas Hardwicke's *Narrative of a Journey to Sirinagur*, in the *Asiatic Researches*, vol. vi. p. 369. and Thibet. (H)

BOOTES, the name of a constellation in the northern hemisphere, containing 23 stars in Ptolemy's catalogue, 28 in Tycho's, 34 in Bayer's, 52 in Hevelius's, 54 in Flamstead's, and 64 in the catalogue published in the *Tables de Berlin*. See ASTRONOMY, p. 705. (W)

BOPAL, or BOPALTAL, a town of Hindostan, and capital of a territory of the same name in the country of Malwa. As the only correct account of this town is that which is given by Mr Hunter, in his *Narrative of a Journey from Agra to Oujein*, performed in the year 1792, we shall make no apology for presenting it in his own words.

"The town of Bopal is extensive, and surrounded with a stone wall. On the outside is a large gunge, with streets wide and straight. On a rising ground, to the south-west of the town, is a fort called Futch-gurh, newly erected, and not yet quite finished. It has a stone wall with square towers, but no ditch. The spot on which it is built is one solid rock. To the south-west, under the walls of this fort, is a very extensive tank, or pond, formed by an embankment, at the confluence of five streams issuing from the neighbouring hills, which form a kind of amphitheatre round the lake. Its length is about six miles, and from it the town has the addition of *tal* to its name. These hills, and others in the neighbourhood, contain a soft free stone, and a reddish granite, the latter of which seems well calculated for buildings that will resist water and the injuries of the weather. It is accordingly used in the new embankment, which is now building at the east end of the lake. From this part issues the small river Patara, and it is said that the Betwah takes its rise from another part of the same.

The town and territory of Bopal are occupied by a colony of Patans, to whom they were assigned by Aurang-Zebe. The present Nawab, Mohammed Hyat, a man about sixty years of age, had, from indolence, love of pleasure, want of capacity, or devotion, resigned the whole administration into the hands of his dewan, who was born a Bramin, but purchased, when a child, by the Nawab, and educated in the Mussulman faith.

The revenue of Bopal is estimated at ten or twelve lacks of rupees. It does not pay any regular tribute to the Mahrattas; but, from time to time, a handsome present is given to conciliate their friendship. The people seem to be happy under the present government; and the dewan, by his hospitality, and the protection afforded to strangers, had induced the caravans, and travellers in general, to take this road between the Deccan and Hindostan." East Long. 77° 28', North Lat. 25° 14'. See *Asiatic Researches*, vol. i. p. 31, 32. (J)

BORDA, JOHN CHARLES, a celebrated French mathematician and natural philosopher, was born at Dax, in the department of the Landes, on the 4th of May 1733. His mother was Maria Theresa de Lacroix, and his father was John Anthony Borda, whose ancestors had acquired considerable distinction in the French army.

The subject of the following article began his studies in the college of the Barnabites at Dax, where he gave early indications of his future genius. Having remained a considerable time at this seminary, he was put under the charge of the Jesuits of La Fleche; and such was his ardour for study, and his superiority of talents, that he very frequently carried off the prizes which were held out as the reward of youthful genius. The Jesuits were not blind to the greatness of his talents, and exerted their utmost endeavours to press him into their order; but his attachment to geometry was too powerful to be weakened by any allurements which the Jesuits could hold out.

The ardour for mathematical research which Borda so early displayed, received an unfortunate check from his father, who was hostile to the prosecution of such unprofitable studies. Borda saw the opposition with which he was to be assailed, and endeavoured to soften it by proposing to enter into the engineer service of the army, where the objects of his profession would necessarily require a knowledge of geometry and physics. His father, however, having eleven children, and being obliged to support two of his sons who were already in the army, was anxious that Charles should look forward to some situation in the magistracy, which might be obtained without much expense and trouble. To these views of his father, Borda reluctantly submitted; but, after having thus lost some of the most precious years of his youth, a friar, who was a particular friend of his father, obtained, by earnest solicitation, the repeal of a sentence which had condemned to perpetual inactivity the genius and talents of his son.

When every restraint was removed, Borda devoted himself to his favourite science; and, in the year 1753, when he was only twenty years of age, he was thought worthy of being introduced to the celebrated D'Alembert. Borda was at this time about to enter into the engineer service, which would have carried him to a distance from Paris; but D'Alembert, who felt an interest in his future progress, wrote to his friends, dissuading them from such a step, and advising him to remain in the capital, and look forward to a situation in the academy. Influenced by this advice, Borda entered the light horse, and continuing his mathematical studies, he became professor to his comrades.

In 1756, he laid before the academy a memoir on the motion of projectiles, which was particularly mentioned in the history of its proceedings; and in the same year he was appointed an associate of the academy.

In the following year he was called into active service, and was present at the battle of Hastenbeck, on the 26th July, 1757, as aid-de-camp to M. de Maillebois. He willingly returned, however, from a species of duty which interrupted the progress of his studies; and upon his arrival at Paris, he became a candidate for a situa-

tion in the engineer service; and such was the estimation in which his talents were held, that he was received without examination, and immediately employed as an inspector of the dock-yards.

This new appointment was particularly favourable for calling into action the peculiar talents of Borda. It inspired him with a fondness for every thing that related to the naval service; and, what seldom happens to the man of genius, he found himself in a situation in which he was led both by his profession and by his inclination to the same line of study.

The first subject of his research was an examination of the theories of the resistance of fluids, a subject intimately connected with the advancement and perfection of naval architecture. The experiments upon this subject made by the Academy of Sciences, were by no means fitted to determine the resistance of bodies that were wholly immersed in the fluid. Borda, however, employed a method which was susceptible of great accuracy, and had also the advantage of ascertaining accurately the velocity of the motion. The surfaces upon which his experiments were made, were of various forms, and the experiments were made both in air and water. The results of these experiments are extremely interesting, and are given at great length in the Memoirs of the Academy for 1763 and 1767. We are compelled, however, to say, that the apparatus employed by Borda was not of his invention. A machine of the same kind had been used some time before by our ingenious countryman, Benjamin Robins, in his admirable experiments on the resistance of air.

We are indebted to Borda likewise for many ingenious experiments and observations on the motion of fluids through different orifices. He prepared a theory of the motion of fluids different from that which had been given by Bernoulli and D'Alembert, and he made new experiments on the *vena contracta*.

In the year 1767, he published an excellent dissertation in the Memoirs of the Academy, entitled, *Memoires sur les Roues Hydrauliques*. In that valuable paper he has shewn, that an undershot wheel produces a maximum effect when its velocity is *one-half* that of the current, though in practice the velocity is never more than three-eighths that of the current. He proved, after Deparcieux, from theory, before Smeaton had determined it by experiment, that the effect of overshot wheels increases with the slowness of their motion; that they are capable of raising, through the height of the fall, a quantity of water equal to that by which they are driven; that undershot vertical wheels produce only three-eighths of this effect; that horizontal wheels produce about one-half of this effect with plain floatboards, and a little more than one-half with curvilinear floatboards.

This memoir of Borda was followed by another, in 1768, on the construction of water-pumps. About this time his attention was directed to isoperimetrical problems, and he had the honour of obtaining the same results as Lagrange, though by a different method.

The last work of our author, which appeared in the Memoirs of the Academy, was a dissertation on the Theory of Projectiles. The immense differences between the theory and the experimental results which had been obtained on this subject, stimulated the ingenuity of Borda. He found, that the range of a twenty-four pounder was diminished nine-tenths by the resistance of the air; and that the diminution would be still greater when the flight of the ball was opposed by wind;

and he has formed a table, shewing the results calculated for pieces of all calibres, for all angles of elevation, and for various ranges and degrees of velocity.

The success and utility of the labours of Borda brought him under the particular notice of M. Praslin, the minister of marine, who was anxious to have the benefit of his talents in the French navy. The practice of the service, however, opposed such a plan, and the officers of the navy naturally resisted a measure which might ultimately prove injurious to their own interests. But M. de Praslin had taken his resolution: He considered the brilliancy of Borda's talents as entitling him to an exception from general usage, and he therefore appointed him sub-lieutenant in the navy.

Borda made his first appearance in his new profession in the year 1768, but, till the year 1771, no events occurred which are deserving of notice. The prizes which were at this time offered, both in England and France, for the improvement of chronometers, to find the longitude at sea, naturally produced in both countries a great variety of inventions. The French government having determined to try the accuracy of some of these time pieces, and of other instruments which were subsidiary to the great object of finding the longitude, the Academy of Sciences appointed Borda and Pingrè as commissioners for making these trials; and they were ordered to sail in the *Flora* frigate, under the command of Verdun de la Cranne. This voyage was performed in the years 1771 and 1772, during which they touched at various places in Europe, Africa, and America, and completely fulfilled the objects for which they were sent out. An account of this voyage was published at Paris in 1778, in 2 vols. 4to, entitled, *Voyage fait par ordre du Roy en 1771 et 1772*, &c. A shorter account of the results obtained during the expedition will be found in the Memoirs of the Academy for 1773.

The zeal and success with which Borda had performed his part in this expedition, pointed him out as the fittest person to be employed in determining the position of the Canary Isles. With this view he was promoted to the rank of lieutenant in 1775, and in the year following he set sail in the frigate *La Boussole*, having under his orders the *Espiegle*, commanded by M. de Puysegur. During this interesting voyage he determined the relative and absolute position of the Canary Isles, by means of several points taken on each, and on the coast of Africa. He verified the height of the Peak of Teneriffè, and calculated tables for finding the position of a ship at sea from the apparent height of this mountain. He examined the peak itself with great care, and brought home with him several mineralogical specimens.

M. Borda was appointed major-general to the naval armament which sailed from Toulon under the Count D'Estaing, and he was present with that distinguished commander at all the naval operations, by which he contributed to the final emancipation of America. In this high situation, the wisdom, prudence, and integrity of Borda excited the admiration of his fellow officers.

From the experience which he had now obtained of the naval service, Borda perceived many defects in the construction of vessels, which could easily be remedied. He considered the want of uniformity in the construction of ships which were to act together as a great defect, from which arose a great discordance in their movements, and in the execution of signals. Upon

his return to France, he communicated this idea to the government, who immediately resolved to carry it into effect. The best form for a ship of 74 guns was selected by Borda from a variety of constructions; and was made the model for the formation of others; and the same plan was followed for vessels of different rates.

In the year 1781, Borda was appointed to the command of the vessel *Le Guerrier*; and in the year 1782, he obtained the command of the *Solitaire*, a ship of 64 guns, for the purpose of escorting a body of troops to the island of Martinique, at a time when the reduction of all our West India islands was the favourite object of the allies, and when they had actually succeeded in the capture of the islands of Nevis and St Christophers. Borda had the good fortune to convoy the troops under his orders to their final destination; and having joined the fleet under the Count De Grasse, he was ordered to a cruising station with the command of several frigates. After he had separated from the fleet, a thick fog came on, and Borda had the mortification to find his little squadron in the middle of eight English ships of war. He tried, in vain, to extricate himself from a force so superior to his own; and when he found that escape was impossible, he refused to surrender till his own ship became a complete wreck. Borda was treated with great kindness and distinction by the English, who sent him back to France upon his parole; but the chagrin which he felt for the loss of his squadron, and the fatigues of three naval campaigns, having begun to produce a serious effect on his health, he determined to spend the remainder of his days in the quiet prosecution of science and philosophy.

During his voyage along with Pingrè in 1771, Borda found, from experience, that the valuable quadrant invented by our countrymen Hadley, was susceptible of great improvement. The celebrated Tobias Mayer had already endeavoured to remove its imperfections. He made the instrument a complete circle, and repeated the measure of the angle on different parts of its graduated circumference. By taking a mean of these measures, he obtained a result independent of the various sources of error to which Hadley's quadrant was liable. M. Lefevre Ginean, the biographer of Borda, declares that the idea of Mayer was never carried into effect, and thus endeavours to ascribe the whole merit of the invention to his own countryman. This statement, however, is completely false; one of Mayer's circles was made for Admiral Campbell by Bird; and Mayer had himself used an instrument for measuring terrestrial angles upon the repeating principle, which is described in the *Commentaries of the Royal Society of Gottingen*, for 1752. tom. ii. p. 325.

Borda having examined, with the utmost attention, the construction proposed by Mayer, soon perceived its defects, which he has pointed out in his *Description et usage du Cercle de Reflexion*, published in 1787. These defects he had, in a great measure removed, in a new circle of his own invention, which was first made in 1777; and which has since been employed with great success, under the name of the *Circle of Borda*. This instrument, however, excellent as it was, had still numerous imperfections; and it was reserved to our ingenious countryman, Mr Troughton, to bring to perfection one of the happiest inventions that was ever made. See ASTRONOMY, p. 678. and CIRCLE.

When the French government had resolved to reform

their weights and measures, Borda was appointed by the Academy one of the commissaries for fixing the basis of the new system. With this view he invented a most simple and ingenious method of measuring, with extreme accuracy, the length of the pendulum; he gave a new form to the rods which were employed for measuring a base in trigonometrical surveys; he employed a most ingenious method of measuring the changes which they suffered from a difference of temperature; and he ascertained the increments in length and bulk which platina, iron, and brass sustained, when the temperature was raised from 1° to 180° of Fahrenheit. Borda was delighted with this national work, and exerted himself with the utmost zeal to bring it to a close. The parsimony of the French government, however, interrupted his progress, and he was often obliged to advance money to the different artists who were employed in this great undertaking, but who had sought in vain for payment from the public treasury. The experiments were at length completed. The conferences with the foreign commissaries were opened, and nothing remained but to enjoy the praise which had been so laboriously earned. Borda, however, was not destined to receive, during his life, that high reward at which genius aspires. The severity of the winter enfeebled his constitution, and brought on a dropsy in the breast, of which he expired on the 20th of February 1799, in the 64th year of his age.

Though Borda devoted his chief attention to the physical sciences and the useful arts, he had a great predilection for poetry and belles lettres; and the *Odyssey* of Homer was his favourite work. The respect which Borda's talents always inspired, was supported by the excellence of his private character. His conversation was agreeable and instructive, and was animated by a vivacity of temper which rendered him a pleasant member of society. Borda was, in 1797, one of the candidates for the office of a director of the French republic; but he did not possess those talents for intrigue, which would have ensured success in such a struggle.

Besides the works which we have already mentioned, Borda drew up, in conjunction with M. Delambre, the *Tables trigonometriques Decimales*, which was published at Paris in 1801.

The account of his voyage to the Canary Isles, drawn up by himself, and full of interesting information, has not yet been published; but we have reason to believe that this work, along with other manuscripts and fragments written by Borda, will soon be given to the world.

(o) **BORDENAVE, TOUSSAINT**, a celebrated French physician, was born at Paris on the 10th April 1728. The profession of a surgeon having been almost hereditary in his family, his father was anxious that it should be continued in the person of his son, and gave him a complete education in languages and philosophy, to qualify him for the situation which he might be called to fill. The progress which he made in the Latin language was so great, that he learned to speak it with unusual fluency; and this circumstance alone gave him great consideration in his own profession, and in the public schools, at a time of life when he could not otherwise have been entitled to receive it.

Bordenave was extremely desirous to have a seat in the Academy of Sciences; and, in the year 1774, he was appointed a veteran associate of that learned body. This appointment being in direct hostility to the rules of the

academy, gave great dissatisfaction; and though Bordenave himself deprecated this mode of admission, the members of the academy were naturally irritated at such an intrusion. The mildness and modesty of Bordenave, however, gained him the friendship of his colleagues, and he enriched the memoirs of the academy with several valuable papers.

Bordenave was created *Echevin* of Paris, and he was the first person who had been elevated to this office. On the birth of an heir to the throne, he was rewarded with the ribbon of the order of St Michael; but he did not long enjoy this honour. He was struck with apoplexy; and, after eight days of suffering, he expired on the 12th of March, 1782.

Bordenave was professor royal and director of the Academy of Surgery, and member of the Imperial Academy at Florence. To the Memoirs of the first of these institutions he contributed many valuable papers on various subjects, in surgery, medicine, and anatomy. In 1756, he published his *Essai sur la Physiologie*, in 12mo, which was reprinted in 1764. In 1757, he published his *Remarques sur l'insensibilité de quelques parties*, 12mo. In 1768, he published a translation of Haller's Elements of Physiology, for the benefit of his pupils. In 1769, appeared his *Dissertations sur les Antiseptiques*, 8vo; and in 1774, he published his *Memoires sur le danger des Caustiques pour la cure radicale des Hernies*. See Haller's *Bib. Chirurg.*; and the *Mem. Acad. Par.* 1782, *Hist.* p. 78. (π)

BORDER. See GARDENING.

BOREALIS, AURORA. See AURORA *Borealis*.

BORELLI, JOHN ALPHONSUS, a celebrated Italian physician and anatomist, was born at Castel Nuovo, in the kingdom of Naples, on the 28th of January 1608. Having been sent to finish his education at Rome, he made rapid progress under the care of Castelli, and acquired such a reputation for his abilities, that he was invited to teach mathematics at Messina in Sicily. In 1647 and 1648, a malignant fever having broken out in that island, and committed dreadful ravages, Borelli paid particular attention to the disease, and published a treatise upon it at Cosenza, entitled, *Delle ragioni delle febbri maligni di Sicilia*, 12mo, 1649. From Messina he went to Pisa, where he was appointed professor of philosophy and mathematics, an office which he filled with great success. The fame of his talents had reached the ears of the Grand duke Ferdinand, and of Prince Leopold, through whose influence he was honoured with a seat in the Academy del Cimento. About this time he began to employ his mathematical knowledge in explaining the functions of the animal œconomy; and we accordingly find, that between the years 1659 and 1664, he wrote numerous letters to Malpighi upon that subject, which were afterwards published in the posthumous works of that learned anatomist.

Having engaged in the revolt of Messina, he was obliged to quit Sicily and retire to Rome, where he lived under the patronage of queen Christina, who was at that time resident in the capital of Italy. The liberality of the Swedish queen, however, does not seem to have been of great extent, as we find Borelli under the necessity of teaching mathematics in the pious schools in the convent of St Pantaleon, where he died of a pleurisy on the 31st December 1679, in the 72d year of his age.

Borelli carried on a correspondence with some of the leading philosophers of his age, particularly with Mr

John Collins, Mr Oldenburgh, Dr Wallis, Mr Boyle, and Malpighi, and was held in high estimation among his contemporaries.

His principal writings are :

1. Delle ragioni delle febri maligni di Sicilia. Cosenza, 1649, 12mo.
2. Della cause delle febri maligni. Pisa, 1658, 4to.
3. Apollonii Pergæi Conicorum, lib. v. vi. et vii. Florent. 1661, fol.
4. De Renum usu judicium, accompanied by Bellini's treatise De structura Renum. Strasburg, 1664, 8vo.
5. Theoriæ Medicorum Planetarum ex causis Physicis deductæ. Florent. 1666, 4to.
6. De vi Percussionis. Bologna, 1667, 4to.
7. Euclides Restitutus. Pisa, 1668, 4to.
8. Osservazione intorno alla vista in eguali degli Occhi, published in the Journal of Rome for 1669.
9. De motionibus naturalibus de Gravitate pendentibus. Regio Julio, 1670, 4to.
10. Meteorologia Ætnæa. Regio Julio, 1670, 4to.

Borelli having been present at the formidable and destructive eruption in 1669, drew up an account of it at the desire of the Royal Society of London, who printed it in their Transactions.

11. Osservazione dell' Eclipsi Lunari 11 Gennaro 1675, published in the Journal of Rome for 1675, p. 34.

12. Elementa Conica Apollonii Pergæi, et Archimedis Opera, nova et breviori Methodo demonstrata. This work was printed at Rome in 1679, in 12mo, at the end of the 3d edition of his Euclides Restitutus.

13. De motu Animalium. This work was published after Borelli's death. The first part appeared in 1680, and the second in 1681. A more correct edition was published at Leyden in 1685, along with John Bernoulli's Mathematical Meditations concerning the Motion of the Muscles. Another edition appeared at Leyden in 1686, under the care of Dr Broen, along with his two pieces, De vi Percussionis, and De Motionibus, &c.

The principal writings of Borelli are, his treatises on the Force of Percussion, and on the Motion of Animals. In the first of these works, he endeavours to demonstrate the proportion between the percussive force, the motion or the velocity of the percussion, and the resistance of the body struck ; and he has not scrupled to say, that he has succeeded in demonstrating the nature, cause, properties, and effects of percussion. In this work he occasionally treats of gravity, magnetism, pendulums, and the tremor of bodies.

Borelli's treatise on the Motion of Animals, which was dedicated to Christina, queen of Sweden, and printed at her expence, exhibits a fine application of the laws of statics to the motion of living beings. He supposes the muscular fibres to be vesicular, and their contraction to arise from the introduction of a portion of the nervous fluid, which mixes with the blood they contain, and by swelling them, shortens their length. He endeavours to measure the individual and the collective power of the fibres which compose a muscle ; and he shews in what measure their power is varied, by the manner in which the fibres are united with the tendons. Varignon and Dr Keill have pointed out some errors in the calculations of Borelli ; but these are quite trifling, when compared with the value and originality of this curious work (π)

BORER. See AUGER.

BORGIA, CÆSAR, one of the most consummate villains mentioned in modern history, was the second

son of Cardinal Roderigo, (afterwards Pope Alexander VI.) by his mistress Vanozza. The year of his birth is unknown ; but he was pursuing his studies at Pisa when Alexander ascended the papal throne, in 1492. He immediately hastened to Rome to congratulate his father on his elevation, impatient to reap those honours which he had it now in his power to bestow. Alexander, instead of welcoming him with the warmth and exultation which his recent prosperity might naturally have inspired, received him with cold formality, admonishing him to repress his rising ambition, and to strive to reach preferment only by the path of virtue. A reception so ill suited to the aspiring temper of Cæsar, and so inconsistent with the known character of his father, at once mortified and surprised him. He retired in the utmost confusion from the presence of his Holiness, and went to seek consolation and advice from his mother. Vanozza exhorted him not to be discouraged, assuring him that she was well acquainted with his father's intentions, and that though he thought it necessary at present to assume an appearance of moderation and disinterestedness, he might confidently hope for every advantage from his indulgence, and his ambition for the aggrandisement of his family. These assurances were immediately confirmed by the promotion of Borgia, who was first made archbishop of Valenza, and, in the following year, appointed cardinal of St Maria Nuova.

Ecclesiastical preferments, however, could not satiate the turbulent and aspiring soul of Borgia, who seemed to feel the clerical habit an irksome, though a very feeble restraint, on the excesses to which his natural depravity prompted him, and longed for some temporal dominion, which might enable him to prosecute more successfully his schemes of ambition, and to yield with less disguise to the wildest impulses of his savage and impetuous temper.

When the army, which Charles the VIIIth of France led against Naples, had entered Rome, and compelled the Pope to a treaty, Borgia was forced to accompany the king as apostolical legate, or rather as hostage for the performance of the stipulated conditions. Finding an opportunity, however, to make his escape, the treaty was broken, and the king obliged to abandon Italy. Vanozza having been plundered by the French army while it lay at Rome, excited both Alexander and Borgia to take a severe revenge for her wrongs. They began by poisoning Gemo, brother to Bajazet, who had fled from that sultan to Italy, as to a sanctuary, and had entered into a league with the French, who intended, after reducing Naples, to undertake an expedition against the Turks. They next proceeded, by means of assassins, to destroy the French who remained at Rome.

While Alexander thus employed Cæsar as the fittest instrument for the execution of his nefarious schemes, he, at the same time, shewed a marked predilection for his eldest son Francis, on whom he conferred all the secular dignities so much coveted by Cæsar, and who, through his influence, had been invested with the dukedom of Gandia, by Ferdinand king of Castile and Arragon. The hatred which Cæsar entertained against his brother, whom he regarded as the greatest obstacle in his career of ambition, was further inflamed by the suspicion, that he rivalled him in the affections of a particular lady. He resolved, therefore, at all hazards, to get rid of so troublesome a competitor ; and accordingly hired four assassins, the chief of whom was Michelotto,

a Spaniard, the most barbarous ruffian of the age, to assassinate his brother, and throw his body into the Tiber. The time which he fixed for the perpetration of this atrocious murder, was the eve of his departure for Naples, to assist at the coronation of king Frederic, in his capacity of apostolic legate. It is said, that when Alexander, overwhelmed with grief for the death of his favourite son, caused the most anxious inquiry to be made after his murderers, Vanozza went to him privately to induce him to give up the search, threatening that if he persisted, he himself should perish by the same hand which had destroyed his son.

About this time, Ferdinand and Isabella complained, by their ambassador, of a dispensation granted by the Pope, for the marriage of a nun, the only heiress to the crown of Portugal, to a natural son of the late king of that country,—a marriage extremely prejudicial to Ferdinand, who hoped to succeed to the Portuguese throne. Alexander, wishing to have Caesar married to Charlotta, daughter to the king of Naples, who was the near relation and faithful ally of Ferdinand, saw how much his interest was concerned in freeing himself from the blame of that dispensation. Florida, archbishop of Cosenza, was therefore accused by Borgia of having forged it; and upon this charge he was immediately thrown into prison, where death, in a few days, released him from his unmerited sufferings.

Soon after this, Louis XII., monarch of France, solicited the Pope for a dispensation to divorce his wife Jane, and to marry Anne of Burgundy, widow of the late king Charles. Borgia eagerly seized this opportunity of promoting his ambitious designs; and having prevailed with his father to entrust him with the dispensation, he resigned his dignity as cardinal, and proceeded as ambassador to the French court. He was cordially received by Louis, who immediately created him duke of Valentinois, granted him an ample pension, and appointed him to the command of a body of cavalry. With the view of extorting still more important favours, Borgia retained the dispensation for some time in his possession, pretending that he had not yet received it from Rome, but was in daily expectation of its arrival. Louis, becoming impatient, applied to the bishop of Setta, the Pope's nuncio at Paris, who assured him, that, notwithstanding the pretences of Borgia, he was certain that he had brought the dispensation along with him to France. Upon this, Louis convened a number of divines, who authorised him to divorce his wife, and to proceed, without further delay, to solemnize his marriage with Anne of Burgundy. Borgia, finding that his schemes were baffled, was obliged, with a very bad grace, to deliver the dispensation; but the discovery proved fatal to the nuncio, whom he carried off by a dose of that poison which he had always ready for administering to those who incurred his resentment, or stood in the way of his promotion.

As Charlotta, acquainted with his infamous character, shrunk with horror from his addresses, he sued for and obtained the hand of the daughter of the king of Navarre, and was honoured by Louis with the order of St Michael. Prosperity, like sunshine to a serpent, seemed only to rouse the inveterate malignity of his nature. Incredible numbers of victims were sacrificed to his revenge or his ambition; and not only in Rome, but in every part of the ecclesiastical dominions, he had assassins in his pay, ready, on the slightest hint, to execute his cruel designs. His father instigated or assist-

ed him in his villainies; and having determined to reduce Romagna into subjection to the holy see, they dispatched a number of the richest cardinals, and seized their property, to enable them to carry on the iniquitous war which they had undertaken. As duke of Valentinois, Borgia was able to levy a considerable force in France, with which he proceeded to Romagna. He commenced his campaign with the siege of Imola and Forli, which soon surrendered. He next reduced Pesaro, Rimini, and Faenza; and, in the year 1501, was honoured, by his father, with the title of duke of Romagna. Unheard of atrocities were committed by Borgia in the course of this war; which he pursued with such vigour and success, that the Italian powers, alarmed for their common safety, formed a combination to oppose him. He contrived, however, to defeat this confederacy by his usual arts of treachery and cruelty. He invited three of the leading men to Senigaglia, under a pretence of negotiating peace, and caused them all to be strangled. Thus Borgia and his father proceeded in their usurpations, alternately courting the friendship of the monarchs of France and Spain, as the influence of either appeared to prevail or decline in Italy. Such was Borgia in his prosperity: a man whom Machiavel proposes as a model of imitation to all succeeding princes, who, like him, might acquire dominions by their valour or address; a man whose talents enabled him to form the most extensive schemes of aggrandizement, and whom no motives of justice, honour, or humanity, could ever move from his purpose.

Providence, as if to counteract the influence of such a pernicious example, condemned him to outlive the greatness which he had so foully acquired; to see his fortune dispersed, and his dominions wrested from him; to see his enemies prosperous and exalted, and himself sunk in the lowest poverty, and the most abject dependence. Poison, which Borgia and his father had prepared for nine wealthy prelates, on whose possessions they wished to seize, was drunk, through mistake, by themselves. The Pope died next day; but the youth and vigorous constitution of Borgia enabled him to recover, though he long experienced the pernicious effects of the poison. He escaped being massacred by the partizans of Pope Pius III., his father's successor, only through the protection of the king of France, whose party he afterwards ungratefully abandoned. Only four of the places which he had usurped now remained in his possession; and these, to secure his personal safety, he offered to resign to Pope Julius II., the successor of Pius III. Julius, though he at first refused them, afterwards ordered Borgia to be seized at Ostia, and confined in close custody till he had again agreed to resign them all. He now sought refuge in Naples; where he was treated at first with some respect by the Spanish general Gonsalvo de Cordova, but was afterwards sent to Spain, in consequence of an order from the king, and doomed to perpetual imprisonment in the castle of Medina del Campo. Here he was closely confined for two years, when, escaping out of a window by means of a rope, he fled to Navarre, where he was received in a very friendly manner by his brother-in-law king John. He intended to have gone from Navarre to France, with the view of engaging Louis to assist him in retrieving his fortune. Louis, however, instead of listening to his proposals, refused to receive him into his territories, confiscated his duchy of Valentinois, and withdrew his pension.

Thus degraded and destitute, he, whose ambition once knew no bounds, was forced to depend for subsistence upon his brother-in-law, who was then at war with his subjects. Cæsar engaged as a volunteer in his service, and was killed in a skirmish before the walls of Viana in the year 1507. His body was stripped by the victors, but was recognised by his servants, who carried it off the field on a horse, and interred it in the cathedral of Pamplona, of which he had formerly been bishop. "Hated in prosperity," says one of his biographers, "scorned in adversity, stripped of all his honours and possessions, even such as he might fairly have claimed, and leaving behind him a name consigned to universal detestation, it would seem that he gained little by being a villain."

He assumed as his motto, *Aut Cæsar, aut nihil*, which gave occasion to many epigrams; with two of which we shall conclude this sketch of his life. The first is written by Sannazarius:

*Aut nihil, aut Cæsar, vult dici Borgia; quidni?
Cum simul et Cæsar possit, et esse nihil.*

The other is by an unknown author:

*Borgia Cæsar erat factis, et nomine Cæsar.
Aut nihil, aut Cæsar, dixit; utrumque fuit.*

See *General Biography. General Dictionary. Gordon's Lives of Pope Alexander VI. and his son Cæsar. Machiavel's Principe*, cap. 7.; and *Mod. Univ. Hist.* vols. xxiv. and xxvi. (k)

BORING MACHINE may be defined to be, any machine for working a borer, or tool, which, by a rotatory motion on an axis, cuts out a hollow cylinder in any substance subjected to its action.

The carpenter's whimble or crank, the drill, pulley, and bow, are, in this sense, boring machines; but custom has confined the term, to signify the apparatus which is used for boring out larger cylinders more quickly and accurately than can be performed by manual labour, but which requires the power of a water wheel, steam engine, or horse wheel, to give it motion. These machines are principally employed for two purposes; for boring wooden pipes for the conveyance of water, and for boring out the metalline cylinders used in hydraulics and in pneumatic engines. In the first case, the whole cavity is removed by the machine, which will be described under the article **PIPE-BORING**; but in the latter, the machine is only used to smooth, and make true, the internal surface of the cylinder, which is cast hollow.

The accuracy of cylinders for pumps, steam engines, blowing engines, &c. is an object of so much importance in the construction of machinery, that many very expensive engines have been made for the purpose. The old and common method is to have an horizontal axis turned slowly round by the mill, at the end of which a borer is fixed, and the cylinder is fastened down upon a carriage, sliding in a direction parallel to its axis, and drawn forwards to the borer by the descent of a weight. The objection to this method is, that any deviation from a rectilinear motion in the carriage will be transferred to the cylinder, and cause it to be crooked; and that the weight of the borer and its axis acting on the lower side only of the cylinder, causes it to cut away more at that part, and render the metal of the cylinder of unequal thickness. This evil, however, was in some measure obviated by a contrivance of Mr John Smeaton, which was a

steel-yard mounted upon a moveable wheel carriage, running within the cylinder. By suspending the weight of the cutter and boring bar from it, the machine was much improved, though still very imperfect.

A boring machine, for metal cylinders, which is not liable to any of these sources of error, is constructed in the manner shewn in Plate LXIV. Figure 5. is a perspective view of the machine in the action of boring out a cylinder for a steam engine; the other Figures explain the construction of its parts, and are drawn to a scale. In Fig. 5. AA denote two oak ground sills, which are firmly bolted down parallel to each other upon sleepers let into the ground. At each end of these a vertical iron frame, BB, is erected, to support the gudgeons at the end of a long cylindrical axis DD, which is turned round by the mill. The cylinder LL, which is to be bored, is fixed unmoveably over this bar, and exactly concentric with it. A piece of cast iron, KK, LL, (Figs. 2, 5, and 4.) called a cutter head, slides upon the axis, and has fixed into it the knives or steelings, *f, f, f*, which perform the boring. This cutter head is moved along the bar by machinery, to be hereafter described; by means of which it is drawn or forced through the cylinder, at the same time that it turns round with the axis D. The steel cutters will necessarily cut away and remove any protuberant metal which projects within the cylinder, or the circle which they describe by their motion, but cannot possibly take any more.

The cylinder is held down upon an adjustable framing, which is readily adapted to receive a cylinder of any size within certain limits. Pieces of iron EE are bolted down to the ground sills, having grooves through them to receive bolts, which fasten down two horizontal pieces of cast iron FF, at right angles to them. These horizontal pieces support four moveable upright standards GG, which include the diameter of the cylinder LL, which is supported upon blocks *bb* below, and held fast by iron bands *aa*, drawn down by screws in the top of the standards GG. The cylinder is adjusted to be concentric with the axis DD, and held firmly in its place by means of wedges driven under the blocks and the standards.

To explain the mechanism by which the cutters are advanced, we must refer to Figs. 2, 3, and 4, by the inspection of which, it will be seen that the axis DD is, in fact, a tube of cast iron hollow throughout. It is divided by a longitudinal aperture *cc*, Fig. 4, on each side. At the ends it is left a complete tube, to keep the two halves together. The cutter head KK, LL, consists of two parts,—of a tube KK fitted upon the axis D with the greatest accuracy, and of a cast iron ring LL fixed upon KK by four wedges. On its circumference are eight notches, to receive the cutters or steelings *f, f*, which are held in, and adjusted by, wedges. The slider K is kept from slipping round with the axis, by means of two short iron bars *ee*, which are put through the axis, and received into notches cut in the ends of the sliders KK. These bars have holes in the middle of them, to permit a bolt at the end of the toothed rack L to pass through. A key is put through the end of the bolt, which, at the same time, prevents the rack being drawn back, and holds the cross bars *ee* in their places. The rack is moved by the teeth of a pinion N, and is kept to its place by the roller O: the axis of the pinion and roller being supported in a framing attached to the standard BB, as shewn in the perspective view of the machine in Fig. 5. The pinion is turned round by a lever put upon the square end of the axis, and loaded with the weight P.

that it may have a constant tendency to draw the cutter through the cylinder. This lever is capable of being put on the square end of the axis either way, so as to force the rack back into the cylinder if necessary.

In some boring machines, another contrivance, superior perhaps to what we have now described, is employed to draw the cutter through the cylinder. It consists of four small wheels, one of which is fixed at the right hand extremity D, of the bar DD, Fig. 4. Another pinion is fastened on the extremity of an axis, analogous to the rack M, having at its outer extremity a small screw, which works in a female screw, fixed to the cutter KK at *c*, (Fig. 2.) Below the second pinion is another, containing the same number of teeth, and fixed on a horizontal axis parallel to DD. At the other end of this axis is a fourth pinion, which is driven by the first pinion at the end of the hollow axis DD. The first pinion has 26 teeth, the fourth 30, and the second and third may have any number, provided they are equal. As the axis DD revolves, the first pinion fixed on its extremity drives the fourth, which, by means of the third fixed on the same axis with it, gives motion to the second. The second pinion being fixed to an axis within DD, unscrews the screw at its other extremity, and of course makes the cutter advance along the cylinder. This screw has eight threads in an inch, and sixty turns of the axis are required to cut one inch.

To introduce a cylinder into its place in the machine, it is necessary to remove the upper braces // of the bearings, upon the standards BB; and by supporting the axis upon blocks placed under the middle of it, the standard, with the pinion N and roller frame, is removed, by taking up the nuts which fasten it down upon the ground sills AA, the rack M being supposed previously withdrawn. A cutter block L, of the proper size to bore out the intended cylinder, is now placed upon the slider K, (Fig. 4.), and wedged fast. The cutter head is then moved to the farther end of the axis, and the cylinder lifted into its place. The standard B is returned, and the whole machine brought to the state of Fig. 5, the cylinder being by estimation adjusted concentric with the axis D. Two bars of iron are now wedged into the apertures *c, c* in the axis, and applied to the ends of the cylinder; while the axis is turned round, they act as compasses to prove the concentricity of the cylinder. Small iron wedges are driven round the cylinder to adjust it with the utmost accuracy; and in this state the cylinder is ready for boring.

The next operation is fitting the cutters, which are fastened into the block L by wedges, and adjusted by turning the axis round, to ascertain that they all describe the same circle. The boring now commences by putting the mill and axis in motion, and the machine requires no attention, except that the weight P is lifted up as often as it descends by the motion of the cutters or steelings. When the cutters are drawn through the cylinder, they are set to a circle a small quantity larger, and returned through the cylinder a second time. For common work, these two operations are sufficient; but the best cylinders are bored many times, in order to bring them to a proper cylindrical surface. The last operation is turning the flaunch *n* of the cylinder perfectly flat, by wedging a proper cutter into the head. This is of great importance, to ensure that the lid will fit perpendicular to the axis of the cylinder. The cylinder is now finished and removed.

The accuracy of this machine depends on the boring

bar DD being turned upon its own gudgeons; and if it is turned to the same diameter throughout, it will certainly be perfectly straight. While the axis is in the operation of turning, a piece of hard wood should be fitted into the grooves in the cylinder. The slider K is first bored out, and afterwards ground upon the axis with emery, to fit as true as possible.

The elevation of a mill proper for moving two of these machines, is represented in Plate LXIV. Fig. 1. The pinion 30 is supposed to be on the axis of a water wheel, and turns the two wheels 60, 60, which have projecting axes, with a cross cut similar to the head of a screw, as is shewn in the Figure.

The ends of the boring axes have similar notches, and by putting keys in between them, the motion may be communicated or discontinued at pleasure, by the removal of the key. (J. F.) (6)

BORMIO, a county in Switzerland, lying at the foot, and in the midst of the Rhetian Alps, upon the confines of the Tyrol and the Grisons. Surrounded on every side by lofty mountains, it has only one narrow opening connecting it with the Valteline, and apparently formed by the river Adda, which flows through it. This opening is named the Serra. The other accesses to Bormio lie across the rugged Alps, which at all times are difficult and toilsome, and in winter frequently impassable. This county, which is about 15 miles in length and 14 in breadth, is divided into five communities or districts; viz. Bormio, including the capital and several dependent villages; the valley of Furba; the valley of Pedinosa; the valley of Cepino; and the valley of Luvino. It formed once a part of the Valteline, from which it was disjoined about the end of the twelfth century, when it became a separate county. After having frequently changed masters, and sustained many destructive wars, it was at length reduced under the dominion of the Grisons, who made a conquest of it in the year 1512. In the new division of Switzerland, recently made by its French conquerors, the county of Bormio, with the Valteline, and Chiavenna, form a part of the Cisalpine republic.

The county of Bormio is, in general, very fertile. Its mountains besides producing considerable quantities of wood, afford excellent pasturage for cattle; and its valleys yield luxuriant crops of grain. It would appear, however, that the rearing of cattle is the principal object of attention; for the inhabitants are obliged to import corn and other articles of provision from different countries. For their wine they are indebted to the Valteline; for corn, to the Tyrol; for corn and rice, to Milan; for linen, to Bergamo and Appenzel; and for cloth, to Germany. Their exports consist of cattle, cheese, and iron, which is obtained from the mines of Frelì, in the plain of Pedinosa, wrought at the expense of a private individual, who enjoys all the profit, after paying a small annual rent to the community. The honey produced in Bormio is of the finest quality. The climate is keen, pure, and salubrious.

The established religion is popery, nor is any other even tolerated. In spiritual affairs, the inhabitants of Bormio are under the jurisdiction of the bishop of Coire. Their priests are held in great reverence, and enjoy peculiar privileges, which extend even to those who wear the clerical habit. Before Switzerland was revolutionised by the French, most of the peasants possessed a small portion of land; and in consequence of the freedom of their government, were much happier than

their neighbours of the Valteline and Chiavenna. Population 14,000. For further particulars relative to the former government of Bormio, the reader may consult the third volume of Coxe's *Travels in Switzerland*. See also *Dictionnaire de la Suisse*. (μ)

BORMIO, the capital of the above county, is beautifully situated at the foot of Mount Braglio, between the rivers Adda and Fredolfo. The internal appearance of the town is very paltry. The houses are built of plastered stone, and some of them would make a tolerable figure, were they not disgraced by the neighbourhood of others with paper windows, or with wooden window shutters in the style of the Italian cottages. The palazzo, or town-house, contains a suite of miserable apartments for the residence of the podesta, or chief magistrate, a chamber for the courts of judicature, and a room in which the representatives of the people assemble. There is here a chapter composed of an arch-priest and ten canons. The Jesuits have had an establishment in this town since the year 1612. About half a league from Bormio are the warm baths of St Martin Melina, in the valley of Premaglia, one of the quarters of the county. They are celebrated for their efficacy in cases of rheumatism, catarrhs, and apoplexy. East Long. $10^{\circ} 21'$, North Lat. $46^{\circ} 17'$. See Coxe's *Travels in Switzerland*. *Dictionnaire de la Suisse*. (μ)

BORN, INIGO, *Baron*, a celebrated German mineralogist, was born of a noble family at Carlsburg, in Transylvania, on the 26th of December 1742. At an early period of life he came to Vienna, where he studied in the college of the Jesuits, who, perceiving the talents of their pupil, prevailed upon him to enter into their order. After remaining a year and a half in this society, he went from Vienna to Prague, where, according to the custom of the Germans, he studied the law. Having completed his course of education, he set out on a tour through Hungary, part of Germany, Holland, the Netherlands, and France, and upon his return to Prague he began the study of natural history and mining, and was received in 1770 into the department of the mines and mint of that city. About the beginning of June 1770, Born set out on a mineralogical tour through the Bannat of Temeswar, Transylvania, and Hungary, of which he gave a detailed account in a series of twenty-three letters addressed to the celebrated Ferber, who published them in 1774. This work was translated from the German by R. E. Raspe, and published at London in 1777. In the first of these letters, dated Temeswar, 14th June 1770, he complains of the loss which he sustained in being ignorant of botany, owing to the want of public institutions in which this science might be taught. "Had I," says he, "besides my little mineralogical science, some knowledge in botany, my three days travelling over barren heaths, from Ofen to Segiden, and thence to Temeswar, might have perhaps procured me an opportunity to entertain you at least with the names and descriptions of some plants. But, alas! I am no botanist, though that is not my fault. You well know how fond I am of natural history: but I never met with any proper opportunity to improve in this part of science. Except at Vienna, there is no academy in all the Austrian States in which botany is taught; nay even at Vienna there is no professor of natural history. For this reason, you need not be astonished that natural history is entirely unnoticed and neglected in Austria, while the English, French, Swedes, and Russians, for the sake of useful science, examine their own and the

remotest countries in the world. But to what purpose these complaints? You may guess by them the dissatisfaction that will attend me in my journey through the mountains of Bannat, Transylvania, and part of the Carpathian hills. All the riches of Flora, during the finest season of the year, displayed in those parts, will be scarce at all enjoyed by me."

Born continued his travels till the beginning of August 1770, when he had nearly lost his life by descending into a mine at Felső-Banya, which brought upon him a disease that embittered the remainder of his life. This accident is so well described in his letter to Ferber of the 22d August 1770, that we are induced to give it in his own words. "My long silence," says he, "is the consequence of an unhappy accident which was very near putting an end to my life. To examine the common firing of Felső-Banya, and the great effects produced by so small an expence of wood, I visited the great mine when the fire was hardly burnt down, and when the mine was still filled with smoke. An accident made me tarry somewhat longer, in the shaft, by which the smoke went off. In short, I lost my senses, and fifteen hours after, I was restored to myself by blisters and other applications. My lips were swollen, my eyes run with blood, and my limbs in general lamed. Without the assistance of a skilful, young physician at Nagy-Banya, and the great care of the upper administration inspector Baron Gerham, in whose house I lodge, you would have been deprived of your friend; and the question is still, whether he is to be saved. A violent coughing, and acute pains in the loins, which alternately put me on the rack, are, I fear, more than sufficient to destroy this thinly framed machine. If that should be the case, then, my friend, I desire you to have my name at least inserted in the martyrology of naturalists." In this wretched state of health, Born travelled with great pain from Nagy-Banya to Schenniz, where he arrived in the beginning of September, and where his family at that time resided. Here he remained during the month of September; and in the beginning of October he set out for Vienna, partly for the purpose of obtaining medical assistance. In 1771 he went to Prague, where he was appointed counsellor of the royal mines in Bohemia, and where he published, in 1771, a treatise written by the Jesuit Poda on Mining Machinery. In 1772, he published his *Lithophylacium Borneanum*, or a catalogue of his collection of fossils, which he afterwards sold to the honourable Mr Greville for 1000*l*.

The reputation of Born now began to extend, and he was honoured with the correspondence of some of the first mineralogists of the age. He was elected a member of the Royal Societies of Stockholm, Sienna, and Padua; and in 1774 he was chosen a fellow of the Royal Society of London.

The talents of Born were not confined to mineralogy alone. He had a taste for general literature, which he displayed, not only in his writings, but in the active zeal with which he laboured to inspire his countrymen with a taste for learning. He contributed largely to a work entitled *Abbildungen Böhmischer und Mährischer Gelehrten und Künstler*, or, *Portraits of the learned Men and Artists of Bohemia and Moravia*. He likewise wrote in the *Acta Literaria Bohemie et Moravia*. He induced government to form a public cabinet for the use of the students at Prague and Vienna; and, in 1775, he founded a literary society at Prague, which has published several volumes, under the title of *Abhandlungen einer Privatge-*

sellschaft in Bohmen, or, Memoirs of a private Society in Bohemia.

The fame of Born was now so great, that, in the year 1776, he was called to Vienna by the empress Maria Theresa, to arrange and describe the imperial collection. In 1778, he published the conchology of this collection in a splendid work, the expense of which was partly defrayed by the empress herself. On the death of the empress the work was discontinued, in consequence of the parsimony of her successor, Joseph II. Some time afterwards, Born was chosen to instruct in natural history the archduchess Maria Anna, for whom he formed an elegant museum. In consequence of these services, he was promoted to the office of actual counsellor to the court chamber in the department of the mines and mint.

The accident which he had met with at Felso-banya now began to produce the most dangerous symptoms. He was attacked with the most excruciating colics, and having, in one of his paroxysms of pain, swallowed an immense quantity of opium, a lethargy was brought on, which lasted 24 hours. The disease now attacked his lower extremities; his feet withered by degrees, and he was unable to walk during the rest of his life.

It was about this time that the freemasons, forsaking the dark mysteries of their order, began to diffuse that light which had hitherto shone in their own lodges, and to take an active part in reforming the abuses and corruptions of society; and Born took an active and prominent part in all their measures. It is impossible to form any idea of a German lodge from those in our own country. The most distinguished literary characters frequented these meetings; and, instead of being regaled with good fare for their appetites, they were instructed by dissertations on history, ethics, and moral philosophy, or on the ancient and modern mysteries of the association. The corruptions of the Romish church, and the exactions of arbitrary power, were among the evils which this society pretended to discuss and reform. Into such societies a few desperate individuals may have gained admission, who were the enemies of all government and of all religion; but these men never directed the foreign lodges, and it never was the object of the German masons to overturn either the church or the state. In the reign of Maria Theresa, these meetings were discouraged; but, upon the accession of Joseph II. the freemasons received complete toleration, and baron Born founded at Vienna the lodge called the *True Concord*. The dissertations which were read at the lodges were afterwards published in the *Journal sur Freymaurer*, or, *Diary for Freemasons*, and were also the foundation of another periodical work, entitled, *Physicalische Arbeiten der eintrachtigen Freunde in Wien aufgesammelt von Born*. Vienn. 1783-7; which was conducted by baron Born and some of the other brethren of the order.

Born was also admitted a member of the Society of the Illuminati; and such was his zeal for the institution, that, when the elector of Bavaria ordered all in his service to renounce the order, Born sent back to the academy at Munich the diploma which he received when admitted among its members.

In the year 1783, when the emperor was making some reforms in the church, Born published a singular work entitled *Monachologia*; which is a severe satire on the

monks, whom he describes in the technical language of natural history. This production is so full of admirable satire, that we cannot resist the temptation of laying before our readers the description of an animal, which, in the course of a few years, may be completely extinct.

MONACHIUS.

Descriptio. Animal avarum, fetidum, immundum, siticulosum, iners, in diem potius tolerans quam laborem; vivunt e rapina et questu; mundum sui tantum causa creatum esse prædicant; colunt clandestine, nuptias non celebrant, fatus exponunt; in propriam speciem sæviunt, et hostem ex insidiis aggrediuntur.

Usus. Terræ pondus inutile. Fruges consumere nati.

In his description of the Dominicans, the same just and severe raillery is happily employed.

Eximio olfactu pollet, vinum et hæresin e longinquo odorat. Esurit semper polyphagus. Juniores fame probantur. Veterani, relegata omni cura et occupatione, gula inulgent, cibus succulentis nutriuntur, molliter cubant, tepide quiescunt, somnum protrahunt, et ex suis dieta curant, ut esca omnes in adipem transcat, lardumque adfiscantur: hinc abdomen prolixum passim præ se ferunt, senes ventricosi maxime estimantur, &c.

The justness of this satire was universally felt; and such was the sensation which it excited, that the archbishop of Vienna complained to the emperor, who replied, that the attack was made only upon the idle and useless part of the order. Being thus supported by Joseph, he published another satire, entitled, *Defensio Physio-phili*, which was followed by his *Anatomia Monachi*. His satirical powers were likewise displayed upon Father Hell, the astronomer, who was a great enemy to the free-masons.

The emperor Joseph at last withdrew his support from the reforming free-masons, and checked them with such restrictions, that they found it necessary to dissolve the society. The influence of Born, however, was not diminished. His great skill in mineralogy and metallurgy raised him high in public opinion, and was of great service to his country. Though the use of quicksilver, in extracting the precious metals from their ores, was long known, yet baron Born was the first person who introduced it on a great scale. At the desire of the emperor, an experiment was made on a large quantity of ore at Schemnitz, in presence of some of the first chemists and metallurgists in Europe. The success of the experiment, and the approbation which he received, induced him, in 1786, to publish his treatise on the Process of Amalgamation, illustrated by engravings of the necessary instruments and machinery.* This process was ordered by the emperor to be adopted in the Hungarian mines, and Born was remunerated for his discovery with one-third of the savings during ten years, and with 4 per cent. of this third part for the next twenty years. The success of this plan excited the jealousy of his enemies, who exerted every nerve in frustrating his views, and in defrauding him of his just reward. Besides the works which we have mentioned, Born published, in 1790, in 2 vols. his *Catalogue methodique raisonnée*, of Miss Raab's collection of fossils. He began a Latin work, entitled, *Fasti Leopoldini*, or a History of the Reign of Leopold II. and also a Treatise on Mineralogy; but he was suddenly seized in the midst of

* This work was translated into English by R. E. Raspe in 1791, in 4to, under the title of "Baron Born's new process of Amalgamation of Gold and Silver Ores, and other metallic Mixtures."

these occupations with violent spasms and cold, which put an end to his existence, on the 28th of July 1791.

"Born was of the middle size," says Mr Townson, "and delicate constitution, dark complexion, black hair, and long black eye-brows. Wit and satire, and a quick comprehension, were marked in his eyes, and his lively and penetrating genius appeared in his countenance. Besides being a good Latin classic, he was master of most European languages of note, and possessed a deal of general information no ways connected with those branches of science required in his profession. He was a great wit and satirist, and a good companion even under the sufferings of bodily pain. His house was always open to the travelling literati who visited Vienna; and unprotected genius was always sure to find in him a friend and patron. He carried this perhaps too far,—so far as to ruin his estate: Probably the expectations of receiving a large income from the amalgamation, made him less attentive to economy in his domestic concerns, though I believe his insolvency was chiefly owing to usurers and money-lenders, to whom he was obliged to have recourse to carry on his expensive projects. Thus, though his patrimony was very considerable, he died greatly in debt. This is the more to be lamented, as he left a wife and two daughters." See Dr Townson's *Travels in Hungary* in 1793, p. 410. Lond. 1797; and Born's *Travels through the Bannat of Temeswar, Transylvania, and Hungary*, in 1770. Lond. 1787. (π)

BORNEO, known likewise by the name of *Bona Fortuna*, the greatest and most important of the Sunda islands, which are Borneo, Sumatra, and Java, was supposed, before the discovery of New Holland, to be the largest island in the world. It has the Philippine islands on the north; Java on the south; Sumatra on the west; and Celebes on the east. It extends from the fourth degree of south latitude to the eighth degree of north latitude, and from 109° to 119° E. Long. It is about 780 miles in length; and its breadth, which is nearly equal throughout, except towards the north, is about 720 miles.

The climate of this island is nearly the same as that of Ceylon. Its extensive forests, and the deep verdure of its fields, preserves a perpetual freshness in the atmosphere; it is exposed neither to hot land winds, as the coast of Coromandel, nor to such violent heats as prevail in Calcutta and Bengal. Here the land and sea breezes are always fresh; or if there be any variation from this general rule, it is occasioned only by particular circumstances which affect the atmosphere in all countries, such as the vicinity of marshes, or the free circulation of the air being prevented by the thickness of the forests.

Few countries can boast of a more fertile soil than that of Borneo; yet such is the indolence and depravity of the inhabitants, that, in spite of the bounty of nature, they live in the most abject poverty. The air of Borneo is the best in all Asia; all the tropical fruits grow here in perfection, besides several other species scarcely known any where else, except at Sooloo, particularly the madang, which resembles a large apple, and the balono, which is not unlike a large mango. The northern part of Borneo is covered with forests of beautiful and very lofty trees, quite free of brushwood. These forests furnish the finest building wood in the world; a black wood, the root of which is very precious; a fragrant wood, such as eagle-wood, ebony, and sandal-wood; besides trees which yield a great quantity of pitch and

rosin. Several kinds of pepper are reared in this island, the most remarkable of which is the vation, whose medicinal virtues are much celebrated. The plantations of pepper belong to the Chinese established in Borneo. They do not, according to the practice of the Sumatrans, conduct the pepper plant around the chinkaree tree; but they fix in the ground a large stake, which supports the plant, without robbing it of its proper nourishment. The Chinese keep the ground between the rows of plants extremely clear; and they often thin the leaves, that the clusters of pepper may be the more exposed to the rays of the sun. A single plant sometimes bears seventy or even seventy-five clusters, which is much more than is ever seen on the pepper plants of Sumatra; a fact which proves incontestibly, what indeed might be naturally supposed, that the chinkaree is extremely hurtful to the pepper tree. Borneo produces likewise abundance of aromatic plants, cassia, camphires, benjamin, and wax. It is thought that spiceries would succeed there well; and, indeed, there are several places in the island where the clove and nutmeg attain all their requisite flavour.

Among the animal productions of Borneo several are peculiar and extraordinary, particularly the oncas, a species of apes, whose body is white and black, and from whose entrails is extracted the most perfect bezoar. The orang-outang is common in the forests of this island; and in some of them there are whole families, or rather flocks of red apes. There is likewise an animal sometimes to be seen here, the fur of which is almost the same as that of the beaver. With the exception of the sparrow hawk, there is no bird in Borneo which resembles those of Europe. The plumage of many of its birds is beautiful beyond description; its parroquets, in particular, have attracted the admiration of every traveller who has visited the country. Goats, swine, cows, horses, and buffaloes, are exceedingly common.

Borneo is scarcely less fortunate in its mineral productions than in the bounty of its soil. Its diamonds have been thought by some persons preferable even to those of Hindostan; though others maintain, that they are smaller than those of Golconda, and that any which are found of a large size, are yellow, and very imperfect. The most productive diamond mines of Borneo are at Ambauwang, beyond Molucca, in the district of Banjarmasin, and at Landac and Pontiana. Diamonds are likewise found in several of the rivers, and are fished up by divers in the same manner as pearls. This fishery is carried on chiefly in the months of January, April, July, and October. Four kinds of diamonds are distinguished by the natives; the white diamonds, which they call *verna ambon*, or white water; the green, which are called *verna loud*; the yellow, named *verna sakker*; and a kind between the yellow and the green, which bear the name of *verna besak*. Many of these diamonds are found from four to twenty-four carats, and sometimes even thirty or forty carats. The total amount of diamonds found in a year seldom exceeds 600 carats. In this island there are likewise found several kinds of metals; iron, copper, tin, and gold. The gold is found chiefly in the state of dust mixed with the sand of rivers. It is said that gold-dust is not only more abundant, but much finer in Borneo than in any other part of the globe. There appears to be no silver in this extensive region; or the unskillful islanders knew not how to explore and work the mines. Hence, if we may credit the accounts of

some travellers, silver is exchanged in Borneo weight for weight with gold; or it we should suspect these accounts of being somewhat exaggerated, they must at least be admitted as a sufficient proof of the great scarcity of silver. In the northern regions of Borneo, there are numerous and very productive quarries of freestone. The centre of the island is occupied by an extensive ridge of mountains, which, from the great quantity of crystal they contain, are called the Crystal Mountains.

At the foot of these mountains there is a large lake, which gives rise to all the rivers that traverse the island. Of these rivers, the most important are the Banjar-massin, Succatana, Lawa, Sambas, and Borneo. The river of Borneo is navigable far above the town of the same name, to vessels of considerable burden; the only difficulty is at the mouth, where the channel is narrow. For the length of a quarter of a mile, it is at the most about seventeen feet broad at high water; but the bottom is sandy and soft, and the river so completely enclosed between the banks, that a vessel which should run aground there, would be in little danger of being wrecked.

On the coasts of Borneo, there is a species of sea-snail called by the natives *swaloo*, which is esteemed a great luxury, and is a pretty lucrative article in their commerce with the Chinese. It is fished by the Biadjoos, the original inhabitants, in seven or eight fathoms depth of water. When the water is clear, they perceive the swaloo at the bottom, and strike it with an iron instrument having four points, fixed along a stone almost cylindrical, but narrower at one end than at the other, and about eighteen inches long. To the end of the stone, near the four prongs, they always attach a ball of iron. The swalloos are likewise procured by diving; the best being always found in the deepest water. The black swaloo is much preferable to the white; but there is a kind more esteemed than either, of a clear colour, and found only in deep water. Swalloos of this kind are sometimes so large as to weigh half a pound; and they are sold at China for forty Spanish dollars the *pècul* (somewhat more than the twelfth of a ton,) whereas the same quantity of white swalloos never brings more than four or five dollars.

This island was at first wholly occupied by the Biadjoos, or Dajakkese; but the incursions of various nations from the continent of Asia, and the neighbouring islands, have obliged them to retire from the coasts, and to take refuge in the interior of the country. The coasts are now inhabited by Malays, Moors, Macassers from Celebes, and Javanese. These people are said to have once extended their dominions as far as Palawan, Manilla, and other parts of the Philippine isles, and even Sooloo is supposed to have formed at one time a part of the empire of Borneo. These distant conquests, together with some traditions current among the Borneans themselves, warrant the belief that they were originally a warlike people, but that they have experienced the fate of many other empires, which, after attaining a certain pitch of greatness, have relapsed into their original condition for want of an active and vigorous government, without which no foreign conquest can ever be preserved. At present they are sunk in the most listless indolence and inactivity, completely destitute of the enterprising courage of their piratical ancestors, and without the least influence over the states of the north of Borneo, which they had formerly subjected to their empire. Thus enervated and un-

warlike, they are at the same time extremely covetous of the private property of one another. Yet they are frank in their dealings, cool and deliberate in their resentments even when they have the power of revenge in their own hands, upright in their intentions, strangers to that polish and acuteness which is called a knowledge of the world, yet by no means deficient in native intelligence, which they have particularly displayed in the perfection to which they have brought the mechanical arts established among them, especially the foundery of bronze cannon: in this art they are superior to all the Asiatics. This character, however, must be understood as applying only to the inhabitants of some parts of the coast, and even of their character we have a darker side to contemplate. They are civilized and refined, indeed, compared with the Biadjoos, and the Idaans or Mooroots, yet they are not altogether free of the barbarities which characterise these rude and savage people.

The Idaans and Biadjoos are the slaves of the most dreadful idolatry. It is one of their religious tenets, that their fate in a future life depends on the number of human beings whom they shall have slain in their combats, or in their ordinary quarrels, and that their happiness or respectability will then be proportioned to the number of human skulls which they have in their possession. The bloody heads which they have been so fortunate as to obtain in their skirmishes, are suspended over their doors as the most honourable trophies.

In order to increase their number of these trophies, they frequently make secret excursions to the river Banjar, and surprise some small vessel belonging to Banjar fishermen. One or two of their unfortunate captives are then sacrificed to their dismal superstition. When they return with a head, all the inhabitants of the village in which they reside, men, women, and children, exhibit the most extravagant demonstrations of joy. Gongs, or musical instruments of copper, are beat by those who conduct the conqueror to his own house, where the women dance around him, and receiving from him the head, force into the mouth some meat and drink: this ceremony is followed by a banquet and dance, after which the head is hung up at the door. The arms of these savages are long knives, and the *soomfihan*, which is a sarbacand or trunk of wood, across which they shoot small arrows poisoned at one end, and charged at the other with a small bit of cork, just thick enough to fill the tube. If one of these arrows only cut the skin, the wound brings inevitable death, unless there be immediately applied an antidote which they generally carry about with them, and which is said to be quite efficacious.

Among the Biadjoos, as in most other savage nations, a person who is inclined to marry, makes it his first object to obtain the consent of the parents, without once consulting the inclinations of his intended bride. Before he can succeed in his suit, he must have proved his courage by cutting off the head of an enemy; and when he is accepted by the parents, he carries to his bride a present, which generally consists of a male or female slave, two dresses and a water-pot, adorned with some favorite figures. On the wedding-day both the parties give a feast at their respective houses; after which the bridegroom, in his best apparel, is conducted to the house of the bride, at the door of which is stationed one of her relations who smears him with the blood of a cock, killed on purpose, and the bride is

smearcd in like manner, with the blood of a hen. They then present to each other their bloody hands, and the solemnity is closed with a second entertainment. Polygamy is unknown among the Biadjoos; and when a wife dies, the husband cannot contract a second marriage till he has again cut off the head of an enemy as an expiation for the death of his wife. If the husband wishes to get rid of his wife, on account of any delinquency, he retains her clothes and ornaments, and makes her pay a fine, amounting to about thirty rials; and each party is then at liberty to marry. When a married woman has committed adultery, the husband, instead of taking vengeance on the adulterer, puts to death two or three of his slaves, and his ignominy is thus removed; the woman is in general punished only with words, though some husbands, more irascible, or more jealous of their honour, proceed to blows. Among the inhabitants of the coasts, the laws relating to marriage are quite different. Like all other Mahometans, they are allowed to marry several wives, though they rarely form alliances with strangers. The punishment of adultery is instant strangulation. The powerful and the wealthy, indeed, set this law at defiance; but it falls with extreme rigour on culprits in the middle or lower classes of the community.

The funeral ceremonies of the Biadjoos partake of the same bloody character as the rest of their superstitious rites. When one of them dies, his body is put into a coffin, and kept in the house until the remaining males in the family have conjointly purchased a slave. When the body is burnt, the slave is beheaded that he may attend the deceased in the other world; and before he is put to death, he receives strict injunctions to be faithful to his master. The ashes of the deceased, together with the head of the slave, are put into a watering pot, and deposited in a small edifice, or tomb constructed for the purpose.

Scarcely any regular form of government prevails among these barbarians. They have no sovereigns; but are ruled by chiefs, whose authority appears to be very circumscribed, and is supported by no written code of laws. Their trials bear a strong resemblance to the trials by ordeal which prevailed in Europe during the dark ages. If a person happened to be accused of theft, and no sufficient proof can be alleged against him, the culprit and the accuser are carried before one of the oldest inhabitants. An earthen pot, containing ashes and water, is placed on the ground; across the pot is laid a piece of wood, on which are put two small copper buttons. An oath is then administered to each party, and the piece of wood is turned round, so that the buttons fall into the water; the accused and the accuser take each one of the buttons, and he is deemed to have succeeded whose button appears as if scowered and whitened by the ashes.

The Biadjoos acknowledge a Supreme Being, whom they worship under the name of *Derwalla*; and to whom, as the creator, preserver, and ruler of the universe, they utter prayers for prosperity in this world, and happiness in the next. If it be considered part of their religious duty to resemble this deity in character, he must be a very gloomy and terrible being; for no nation on earth can equal the Biadjoos in their thirst for blood, and their propensity to revenge. Though they have no kings of their own, they recognise the sovereignty of the sultan of Banjar-massin, to whom they

pay annually a tribute in gold dust to the value of 20 rials.

The Moors, who have taken possession of the coasts of Borneo, are much more civilized, living under regular governments, and restrained by well defined and certain laws. Their territories are divided into several distinct kingdoms; Banjar-massin, Succatana, Landac, Sambas, Hermata, Jathou, and Borneo. The largest of these kingdoms, and the most important, on account of its connection with the Dutch East India Company, is that of Banjar-massin on the southern coast, (See BANJAR-MASSIN.) Cagu-Tangie was formerly the residence of the sultans of that kingdom; but, in the year 1771, the Sultan Sasubhannan transferred the seat of his court from that place to Martapura, where he caused a large city to be built, and a canal to be conducted through the middle of it; and, at the same time, he changed its name from Martapura to Buni-Kintjana. The Dutch factory is situated at the end of the village of Tatas, or Banjar-massin. It is protected by a fort of an octagonal form, surrounded by palisades, and furnished, on the east side next the river, with three bastions, and with two on the west or land side. For the productions of the country valued in commerce, which are copper, gold, diamonds, canes, birds nests, wax, *pedra del porco*, dragons' blood, and iron, the Dutch give in exchange, agates, rings of red agate, different kinds of coral, coarse porcelain, silk of various colours, all kinds of cotton cloth, such as are worn by the Indians, various productions of Java, and opium, which, being prohibited by the sultan, is privately smuggled. At the town of Banjar-massin there is a manufacture, or more properly, a dock-yard, for junks; one of which, loaded with the commodities of the country, may be had at a very low price.

The kingdom of Succatana lies about 50' south of the equator, having a little to the north the river Pontians, which discharges itself into the sea under the line through several mouths. At the distance of about seven or eight miles from the sea the river separates into two branches. It has about twelve feet of water at its mouth, and at high water sixteen; so that small vessels can proceed, with great ease, up to the company's factory.

On the northern arm of the Pontiana lies the kingdom of Landac, in north latitude 35'. Here the Dutch had a factory about a century and a half ago; but they were soon after completely driven out of their possessions, which they never recovered till the year 1778, when the king of Bantam, to whom Landac and Succatana then belonged, made a grant of these kingdoms to the Company. The Dutch had no sooner obtained possession of them, than they built a fort at Pontiana, between Landac and Succatana, and appointed Pangarang Saidja Nata regent of the whole district. From that time they have accounted these lands their own property, and the princes who govern them as their vassals. The capital of Landac, which is the residence of the prince, is situated on the projecting point of a mountain, to which there is an ascent by 118 steps. On the right and left of this mountain flow two rivers, so full of rocks as to be totally unnavigable, so that the place is by nature, impregnable; and, to give it additional security, it is well furnished with artillery. Between Landac and Borneo there are several smaller kingdoms, as yet but little known; the petty sovereigns of which are vassals of the sultan of Borneo.

The civil government of the kingdom of Borneo is exercised by a sultan, and a superior council, composed of those pangarangs who are invested with the high offices of state : such as the *bandahara*, who is entrusted with the executive power; the *degadong*, or chamberlain of the sultan's palace; the *tomongong*, or general in chief of the armies; the *pamancha*, or judge in law pleas; and the *shabander*. The government of Borneo bears a very striking resemblance to the ancient feudal system which prevailed in Europe. The prerogative which the sultan enjoys, of naming, in his own right, all the great officers of state, will always, indeed, make his authority respected, and give him a great influence in the councils; yet every pangarang exercises an absolute power over his particular vassals, who never fail to espouse his cause, even though he should happen to oppose his sovereign. They have no particular laws against treason. Murder is punished with death, except in the case of a master killing his slave. Theft, according to the enormity of the offence, is either punished capitally, or by the amputation of the right hand. They have no positive laws relative to commerce; a defect which must be ascribed to their want of communication with any other nations except the Chinese, who pay to the chiefs of Borneo presents, which appear to be a kind of tribute. The Chinese, who are settled here enjoy tranquilly the fruits of their industry; but those who carry on an occasional traffic are exposed to many hardships, from the want of laws to compel the debtor to discharge his debts, and from the necessity of yielding to the most unreasonable demands of those who are invested with authority.

The Portuguese, who first discovered Borneo in 1526, wished to form a settlement on its coasts. As their military force was too insignificant to inspire terror into the natives, they endeavoured to secure the good will of one of the sovereigns of the country, by presenting him with some beautiful pieces of tapestry, on which human figures were very curiously wrought. The sovereign, conceiving these figures to be enchanted men, who might have some fatal designs against him, sent them back with horror, and expelled the Portuguese from the country. They soon after effected a settlement there, but were all massacred by the suspicious inhabitants. In the course of the 17th century, their merchants from Macao carried on a pretty free commerce to Banjar-massin; and even obtained permission, about the year 1690, to establish there a factory. Their counting-house was scarcely built, however, when it was pillaged by the Moors, who murdered the director and the commissaries, took their vessels of Macao in the harbour, and butchered the crews. This disaster effectually deterred the Portuguese from all further attempts to establish a commercial connection with Borneo.

The Spaniards, established in the Philippine islands, were no less eager than the Portuguese to engross the commerce of Borneo. The port of Borneo, the ancient capital of the island, was for several years in their possession. They had concluded an advantageous treaty with the sultan of that kingdom, who engaged himself to shut the ports under his controul against all other European nations, and to make war against all the enemies of Spain. They found it expedient, however, to abandon that establishment, either because it was too distant from the Philippines, or on account of the rude treatment which they received from the Moors, who

were no less cruel and suspicious than those of Banjar-massin.

The bad success of the Spaniards and Portuguese, did not deter the Dutch from attempting to form settlements on an island which seemed to combine so many commercial advantages. They, at first, succeeded in establishing factories at Borneo, Sambas, and Succatana. But the persecutions of the Moors forced them likewise to abandon these inhospitable coasts; nor do they seem to have ever revisited them till the year 1748, when they appeared off Banjar-massin with a squadron, which, though feeble, so overawed the sultan, that he granted them the exclusive commerce of pepper, with this single exception, that he should be permitted to deliver 500,000 pounds of that commodity to the Chinese who frequented his harbours. The advantages which the Dutch derived from this commerce scarcely counterbalanced the expense of the establishment.

The English, like the Dutch, were tempted, by the advantages which Borneo held out, to brave all the dangers which other Europeans had experienced in endeavouring to settle on its coasts. They, accordingly, began by establishing a colony at Succatana; which, like all their predecessors who had made the same attempt, was compelled to leave the island in 1694. A short time after that, however, they were received at Banjar-massin; where, with the assistance of two hundred Indian families, who placed themselves under their protection, they rapidly formed a very flourishing colony. The Moors, envious or afraid of the growing prosperity of this factory, were approaching one day to plunder and destroy it, when the captain of an English vessel, who had come by accident to Banjar-massin, dispersed the barbarians, and pursued them along the river as far as Nagra, about sixty leagues from the mouth of the Banjar. The factory was no longer molested by the natives; but the English, destitute of money and of victuals, were obliged to abandon it. They returned, however, in 1704, with a fleet of several ships, which enabled them to give law to the islanders. Captain Barr was ordered to take the direction of that establishment, and to build a fortress upon the banks of the Banjar. Alarmed by that undertaking, the Moors advanced upon the river with a numerous flotilla to attack the factory; but Barr, proceeding against them with a single vessel, terrified them to such a degree by the fire of his artillery, that they fled in all directions.

The death of that brave and active man, in 1706, was immediately followed by the total destruction of the English factory. Cunningham, his successor, was a mean and dastardly wretch, afraid to encounter the slightest danger, and unable to provide against the most trifling contingency. The Moors, no longer kept in awe by the name of Barr, again appeared in arms before the fortress; when its infamous governor, without making one effort to defend it, embarked with all the garrison, and set sail for England, abandoning, to the discretion of the enemy, not only all the goods and ammunition of the factory, but a number of workmen and slaves attached to its service. The Moors pillaged and sacked the fort, massacred all the Indians whom they found there, and, soon after, drove from Tamborneo, at the southern extremity of the island, a remnant of English who had settled in that quarter. Such was the disgraceful manner in which the British colony in Borneo was completely destroyed.

They again attempted, in 1766, to form a settlement

in the island of Balambangan, at the northern extremity of Borneo, which was ceded to them by the king of Soloo. They stationed there a few Europeans, and a garrison of 300 soldiers, Europeans and blacks, and designed to establish a factory, where they might exchange the productions of Europe and Hindostan for those of China and the Indian islands; but, in the year 1772, their garrison was greatly reduced by contagious diseases, and the fort which they had constructed, being badly fortified, was suddenly attacked, and the whole establishment was destroyed. Yet the English have still a factory at Borneo, and are masters of all the northern coast of the island, which was delivered up to them by the Soloos, who had conquered it. The places ceded to the English to the south of Pirates Point are, Pandassan, Tampassook, Abia, Amboug, Salaman, Tawarran, Jannan, and Palatan as far as Keemanees. In this extent of coast there are some good harbours; and it is much more populous than the country north of Pirates Point, which extends a little beyond the spacious harbour of Sandakan as far as Towson Abia, where the English possessions in this island terminate.

Mr Dalrymple, in a plan which he has given for forming an establishment at Balambangan, expresses his conviction, that the Idaans, if they were well treated, would eagerly crowd in from all quarters, to place themselves under the protection of any Europeans who should settle in their neighbourhood. His opinion is supported by Mr Forrest, a very judicious navigator; who adds, that if an English establishment should be formed in that quarter, these people would supply them abundantly, by their different rivers, with pepper and rough materials for exportation, besides the precious articles of gold and diamonds; not to mention the great advantages which a free commerce between this island and Hindostan would afford to Bengal and Bombay. There might be there trained a race of Lascars, or mariners, who would employ a great number of vessels; because the commodities which are exchanged for the salt and embroidered cloths of Hindostan are of great bulk. These Lascars, mingled with an equal number of English seamen, would fight a vessel well, as has been often experienced in India, especially on the coast of Malabar. Another advantage resulting from this establishment would be, the ready communication which it would open with Cochin-China, and other places on the eastern shores of the China seas. As the track is nearly north-west or south-west, every trade wind would furnish a favourable gale for sailing thither from Borneo or Balambangan, and even for returning; and Cochin-China would afford a ready market, not only for woollen stuffs, but likewise for the cottons of India, and particularly the muslins of Bengal.

Long before Borneo was known to Europeans, the Chinese had established an extensive commerce with that island, which they still continue. This commerce resembles, in some measure, the trade of Europe with America. The Chinese export from Borneo great quantities of wood, which they employ for making furniture, and which they purchase for about two dollars the pécül, and sell for five or six. They likewise export junks, a kind of resin, cloves, swallows, tortoise shells, birds nests, and camphor, which is much superior even to the camphor of Sumatra. A great proportion of this precious drug comes from those districts of Borneo which have been ceded to the English by the Soloos. In return for these commodities, the Chinese import every descrip-

tion of their national manufactures or workmanship, and keep open shop, not only on shore, but likewise on board their junks.

The bay of this island is very spacious, and has a gulf in the form of an arm of the sea, interspersed with several islands. The water is every where deep, and is never more agitated than a lake or a river. See *Transactions of the Batavian Society; Merkwürdigkeiten aus Ostindien; Valentyn's General Description of India; Salmon's Present State of all Nations; Prevost's General History of Voyages; Oriental Repository; Forrest's Voyage, &c.; and Puchet's Dict. de la Geog. Commerc.* (k)

BORNEO, a sea-port town in the island of Borneo, and capital of the kingdom of the same name, is situated about ten miles from Pulo Chirring, on the north-west side of the island. It consists of about 300 houses, built upon piles along the two banks of the river Borneo, and the houses are entered by ladders and stairs. On the left the houses stretch towards the land, upon a narrow point or cape. There is little communication from house to house by land, because there is no road, and the ground is very marshy; the intercourse is principally carried on by boats and sloops on the river. On the right, the houses advance half a mile into the land, with canals, in the form of streets, between their rows. It appears as if, before the houses were built, the river formed here a large but shallow basin, on which have been erected three-fourths of the town, which, in that circumstance, resembles Venice, with a great number of streets of water, so to speak, at right angles, and parallel to the river, which is here as large as the Thames at London bridge, with six fathoms of water in its channel. In these divisions of the town by canals there is neither firm land nor island, the houses being entirely built on piles in shallow water. The public market is held sometimes in one place, and sometimes in another; and consists of a number of boats loaded with the necessaries of life, and the various articles of merchandise, and crowds of purchasers rowing up and down the river. (k)

BORNHOLM, the most eastern of the Danish islands in the Baltic, is situated between Scania and Rugen, about 16 miles from the extremity of Zealand. It is about 6 miles long and 3 broad, and extends from north-east to south south-west.

Though the soil of Bornholm is rather stony, yet it produces all sorts of grain. From the excellence of the pasturage, the inhabitants export a good deal of butter, and rear a considerable number of sheep, the wool of which is spun and used in the island.

Bornholm abounds with excellent pasture, which is superior to that of Gotland and Bremen; and it possesses also a kind of coal, which is equal to the coal of this country. Clay proper for potteries, and particularly useful in the manufacture of porcelain, is also found here. In a kind of globular stone common in Bornholm, are found small crystals called diamonds of Bornholm.

The inhabitants of this island have a peculiar method of curing and smoking salmon, which are sent to Copenhagen, and are held in high estimation. Herring and cod are caught in great numbers.

There are no fewer than six little towns in this island, of which Sandewick is the principal. Large farm-houses are scattered over every part of the island, which renders it extremely populous. The inhabitants are pro-

prietors of the soil, and are remarkably jealous of their rights and privileges. Population 30,000. E. Long. 15°, N. Lat. 55° 10'. (a)

BORNOU, an extensive empire in the interior of Africa, situated to the south-east of Fezzan, and bounded on the north by the desert of Bilma; on the west by Nubia, Kuka, and Tagua; on the south by Kanga and Begernce; and on the east by Cassina, Zegzeg, and Zanfara. This country, which extends from the 26° to the 22° north latitude, is numbered by the Mahometans among the four most powerful monarchies in the world,—the other three are Turkey, Persia, and Abyssinia. Bornou is the name by which it is known among the natives, but it is called by the Arabs, Bernou, or Bernoah, the land of Noah, because they believe that it was on the mountains of this country that the ark rested after the deluge.

The climate of Bornou, as might be expected from the position of the country, is excessively, though not uniformly, hot. The year is divided by two seasons, the first of which, commencing about the middle of April, is introduced by violent winds from the south-east and south, bringing with them an intense heat, a deluge of sultry rain, and tempests of thunder and lightning, which destroy multitudes of the cattle, and not a few of the people. The rainy period continues from three to nine successive days with short intervals, from the occasional shifting of the wind to the north or west. During this period, the inhabitants confine themselves closely to their dwellings; but the rest of the first season, however sultry or wet, does not suspend the labour of the fields. With the commencement of the second season towards the end of October, the ardent heat subsides; the air becomes mild; the weather continues serene; and, as the year declines, the mornings, before sunrise, are unpleasantly cool.

The soil of Bornou is, in general, amazingly fertile, though frequently interrupted by stripes of barren sand. The grain, which is principally cultivated there, is the Indian corn, of two different kinds, distinguished by the names of the gassob, and the gamphuly. The gassob, which, in its general shape, resembles the common reed, is of two species; the first grows with a long stalk, that bears an ear from eight to twelve inches long, and containing, in little husks or cavities, from 300 to 500 grains, of the size of small pease. The second species, which is common in Tripoli, differs from the first only in the shorter size of its ear. The stalk of the gamphuly is much thicker than that of the gassob; its ears are more numerous, for it has several on the same reed, and the size of its grain is considerably larger. This is the same kind of corn which is frequently seen in Spain, and which is there called maize. Wheat and barley are not raised in Bornou; but the horse-bean of Europe, and the common kidney-bean, are cultivated with much assiduity, as they are used for food both to the slaves and to the cattle. Gum trees are thinly scattered throughout the country. Cotton, hemp, and indigo, are produced in great abundance. In the agriculture of Bornou, the plough is unknown, and the hoe is the only instrument employed. In the labour of husbandry, the men are always assisted by the women. While the former open the ground with their hoes, and form the trenches in straight parallel lines, the women follow and throw in the seed, and as soon as the weeds begin to rise where the grain has been sowed, it is their business to root them up with the hoe.

The sowing season commences when the periodical rains of April have ceased; and so rapid in that climate is the vegetation, that the gassob is reaped early in July; but the gamphuly, of slower growth, is seldom cut down till the month of August or September.

Besides the vegetable productions already mentioned, two species of roots are used by the inhabitants of Bornou, which constitute a wholesome and substantial food. The one called *dondoo*, produces a low plant, with branches that spread four or five feet upon the ground, and leaves resembling those of the garden-bean. In five months, after it has been planted, the leaves fall off, and the root is taken from the ground, and being cut into small pieces, is dried in the sun, in which state it may be kept for two years. Before being used as food, it is reduced to a fine powder, and mixed with palm oil till it assumes the consistency of paste. The other root is that of a tree, with the name of which we are unacquainted. It is prepared for use by boiling, without any further process.

The fruits of Bornou are as delicious as they are abundant. The most common species are grapes, apricots, and pomegranates, lemons, limes, and water and musk melons. There is a valuable tree called the Kedeynah, indigenous, and, as far as we know, peculiar to this country, in form and height resembling the olive, and the lemon in its leaf, and bearing a nut, of which the kernel and shell are both in great estimation, the first as a fruit, the last on account of the oil extracted from it, which the people of Bornou burn in their lamps as a substitute for the oil of olives.

The supply of animal food in Bornou, is even more ample and varied than its vegetable stores. Innumerable flocks of sheep, and herds of goats and cows, with amazing numbers of horses, buffaloes, and camels, (the flesh of which is highly esteemed,) brouze on the vales and the mountains of this favoured country. The common fowl is also reared by the inhabitants; and their bees are extremely numerous. Their game consists of the huaddee, and other species of antelopes, the partridge, the wild duck, and the ostrich, the flesh of which they prize above every other. Their other wild animals are the lion, the leopard, the civet cat, the small wolf, the fox, the wild dog, with which they hunt the antelope, the elephant which is rare, and of which they make no use, the crocodile, the hippopotamus, and a large and singular animal called Zarapat, which is described as resembling the camel in its head and body, as having a long and slender neck like the ostrich, as being much taller at the shoulder than the haunches, and as defended by so tough a skin, as to furnish the natives with shields that no weapon can pierce. Like all countries in similar latitudes, Bornou is much infested with dangerous or loathsome reptiles, especially snakes and scorpions, centipedes and toads. The camel, the horse, the ass, and the mule, are common throughout the country; the dog which they employ in hunting their game, appears to be their only domestic animal.

In Bornou, the houses are similar in form to those of Tripoli, and throughout the whole empire the same mode of building prevails. Four walls inclosing a square, are first erected; within these, and parallel to them, are built four other walls; the intervening space is then divided into different apartments, and covered with a roof. Thus the space within the interior walls determines the

size of the court; the space between the walls determines the width of the apartments; and the rooms are of the same height as the walls. On the outside of the house there is usually a second square or large yard, surrounded by a wall, for the accommodation of the cattle. In the construction of the walls, the following method is invariably adopted: A trench being made for the foundation, is filled with dry and solid materials, rammed in with force and levelled; over these is placed a layer of tempered mud or clay, in which are regularly fixed a proper number of stones. Thus with alternate layers of clay and stones, the wall is raised to the height of six or seven feet, when the workmen suspend its progress for a week, that it may have time to settle, and become compact; for which purpose they water it every day. The roofs are formed of branches of the palm-tree, intermixed with brushwood, and covered with layers of earth in such a manner as at first to be water proof, though the violence of the wind and rain generally destroys them before the end of the second year. The whole building is white washed with a species of chalk.

Though the symmetry of the houses, and their general resemblance to each other, would easily have admitted of a regular arrangement of streets, yet all the towns of Bornou consist of houses straggling wide of each other, and placed without method or rule. "The obvious propriety of giving to the principal mosque a central situation, exhibits the only proof of attention to general convenience." The towns, in general, have no external defence; but Bornou, the capital, is surrounded by a wall of fourteen feet in height, the foundations of which are from eight to ten feet deep, and which seems to be very firmly built. A ditch surrounds the whole; and in the wall there are four gates, opening to the east, west, north, and south, which are carefully shut every evening at sunset, to protect the inhabitants from any sudden surprise.

Less attention is paid to the furniture of the houses than to their structure. Among the lower classes, the only articles of furniture are mats covered with a sheep skin, upon which they sleep, an earthen pot, a pan of the same kind, two or three wooden dishes, two wooden bowls, an old carpet, a lamp for oil, and sometimes a copper kettle. Besides these utensils, the richer inhabitants possess leathern cushions stuffed with wool, several brass and copper vessels, a handsome carpet, and a sort of candlestick; for instead of vegetable oil, which is used by the common people, they employ the light of candles manufactured from bees wax, and the tallow of sheep.

The wide dominions of Bornou are peopled by a countless multitude, among whom no fewer than thirty different languages are spoken. The language which prevails in the capital, bears a strong resemblance to that of the neighbouring negroes; but the nobles and principal families converse in Arabic. They are acquainted with the art of writing, and are taught to express the Bornou tongue in Arabic characters. The natives are represented as singularly courteous and humane. They will not pass a stranger on the road without stopping to salute him; their houses are ever open for the reception of visitants; and their sharpest quarrels are mere contests of words. Passionately fond of the amusement of drafts, they often sit down upon the ground, and forming holes to answer the purpose of squares, supply the place of men with dates, or the

meaner substitute of stones, or camel's dung. On the event of a game, they stake their whole property, sometimes even their clothes; and as the bye-standers constantly take sides, and obtrude their advice, the whole groupe presents the most ludicrous scene of violent gesticulation and clamorous abuse. Persons of superior rank devote themselves to chess, in which they are said to be eminently skilled. The sultan of Bornou, and his court, profess the Mahometan faith; but the majority of the people adhere to the idolatrous superstitions of their fathers.

The monarchy, as in the empire of Bathna, is elective; but the election is confined to the royal family. On the death of a sovereign, the privilege of choosing a successor among his sons, without regard to priority of birth, is conferred by the nation on three of the most distinguished men, whose age and character for wisdom are denoted by their title of elders, and whose conduct has entitled them to the public esteem. Limited in their choice by no other restriction than the necessity of electing the most worthy, they retire to an appointed place, the avenues to which are carefully guarded by the people; and during their deliberations, the princes are confined in separate chambers of the palace. When their choice is determined, they proceed to the apartment of the sovereign elect, and conduct him in silence to the place where the corpse of his father, which cannot be interred till this awful ceremony is passed, awaits his arrival. There they expatiate freely on the character of his departed parent, and conclude with this awful warning, "You see before you the end of your mortal career; the *eternal* which succeeds to it, will be miserable or happy, in proportion as your reign shall have proved a curse or a blessing to your people." The new sovereign is then brought back to the palace, amidst the loud acclamations of the multitude, and is invested by the electors with all the slaves, and two-thirds of all the lands and cattle of his father; the remaining third being always kept as a provision for the other children of the deceased monarch.

Fatal dissensions in the royal family, are the almost inevitable consequences of this mode of election. As soon as the sovereign is invested with the ensigns of royalty, such of his brothers as have reached the age of manhood, prostrate themselves at his feet, and rising, press his hands to their lips in testimony of their allegiance. If their sincerity be doubted, either by the king or the elders, they are either removed by death, or doomed to perpetual imprisonment: when they are not suspected, they receive from the reigning monarch a liberal allotment of lands and cattle from the possessions of their father, together with presents of slaves. Such of the princes as are too young to receive their proper portion of their father's property, are educated in the palace, till they arrive at the years of maturity, at which time their respective shares of land and cattle are assigned them. It often happens, however, that the most popular, or the most ambitious of the rejected princes, veiling his designs under the affectation of zealous attachment, creates a powerful party, and, assured of foreign aid, prepares in secret the means of revolt. "But stained with such kindred blood," says the writer who has drawn up the account of Bornou from Mr Lucas's communications, "the sceptre of the victorious rebel is not lastingly secure—one revolution invites and facilitates another; and till the slaughter of the field, the sword of the executioner, or the knife of the assassin,

has left him without a brother, the throne of the sovereign is seldom firmly established."

In Bornou, as in every Mahometan empire, the administration of the provinces is committed to governors appointed by the crown; and the expences of the sovereign are defrayed partly from his hereditary lands, and partly by taxes levied on the people. The monarch of Bornou is not, like the sovereign of many neighbouring kingdoms, the executioner of the criminals whom his own voice has condemned; but commits the care of executions to the cadi, who directs his slaves to strike off the head of the prisoner.

The military force of this empire consists chiefly of cavalry, armed with the sabre, the lance, the pike, and the bow, and defended by shields of hides. Fire arms, though not entirely unknown to them, are too difficult to be procured for common use. When the sultan levies an army for the purpose of taking the field, he is said to have a custom of causing a date tree to be placed as a threshold to one of the gates of his capital, and commanding his horsemen to enter the town one by one, that the parting of the tree in the middle, when worn through by the trampling of the horses, may serve as a signal that the levy is complete.

The inhabitants of Bornou, though composing so many different nations, are alike in their appearance, having a black complexion, but features different from those of the negroes. Their dress consists of a girdle for the waist, a turban, consisting of a red woollen cap, surrounded by folds of cotton, together with a loose robe of coloured cotton, of a coarser kind.

The only manufactures known in Bornou are coarse linen, made from the hemp of the country, and calicoes and muslins woven in pieces of about nine inches in breadth, and varying in length from fifteen to twenty yards. These cotton manufactures, when enriched with the blue dye of the country, which is preferable to that of the East Indies, are valued more highly than silk. They also manufacture a species of carpet, which they use as a covering for their horses; and a coarse cloth from wool, mixed with the hair of goats and camels, of which they make tents for the use of the army. The little silver they have is converted by their own artists into rings; and from native iron ore they fabricate, though unskilfully, such tools as are employed in their rude husbandry. Their articles of exportation are gold-dust, slaves, horses, ostrich-feathers, salt, and civet; in return for which they receive copper and brass, which are brought to them from Tripoli, and are used as the current species of Bornou; imperial dollars, which are likewise brought from Tripoli by the merchants of Fezzan, and are converted by the artists of Bornou into rings and bracelets for their women; red woollen caps, which are worn under the turban; check linens; light coarse woollen cloths; baize, barakans, small Turkey carpets, and plain Mesurata carpets. See *Proceedings of the African Association*, chap. vi. and xii.; *Discoveries in Africa*; and *Browne's Travels in Africa*. (k)

BORNOU, the capital of the above empire, is situated about 600 miles south-east of Morzouk, and 420 miles west of Sennaar. It is a town of greater extent than Tripoli; but the houses are so irregularly placed, that the spaces between them have no appearance of streets. The king's palace, surrounded with high walls, forms a kind of citadel, and is built in a corner of the town. Provisions are sold in public markets within the city; but for other articles, a weekly market is held, as in Barbary,

without the walls. Near this city there runs a small river, which falls into the Banr-el-gazalle. East Long. 25° 10', North Lat. 19° 45'. (k)

BOROUGH, or BURGH, (Sax. *Borge*, *Borgh*, or *Bor-hoe*; Germ. *Burg*; Lat. *Burgus*.) is a term frequently used to denote a corporate town, which is not a city; but, at present, it is more commonly applied to a town, whether corporate or not, which possesses the privilege of sending representatives to Parliament.

By some etymologists and antiquarians, the term *borough* is supposed to have been primarily applied to a *tything*, or small community, consisting of ten families, who were mutually bound as pledges for the good behaviour of each other; and this conjecture derives some plausibility from the subdivision of the counties in England into hundreds, and tythings, or towns, which appears to owe its origin to Alfred, (Hume's *Hist.* ch. ii.), and from the similarity of the term to the word in the Teutonic dialects, (*bürge*, *bürg-shaft*.) signifying, pledge or security. In fact, these tythings, decennaries, or fri-bourgs, afterwards received the name of *frank-pledges*. It may be observed, however, that, to this day, the word *burg* in the German language, signifies a castle or place of strength; which seems to confirm the observation of Verstegan, that the term *borough* denotes a town, having a wall or some kind of inclosure about it; so that all places which, among our ancestors, had the denomination of borough, were, in one way or other, fenced or fortified. Indeed, it is evident, that, at the period when towns began to be formed, in modern times, they must either have been in some manner fortified themselves, or placed within the protection of a nobleman's castle or residence.

But, leaving the obscure labyrinth of etymological conjecture, it is of more importance to inquire into the origin and progress of towns and communities, which have had such a decided influence on European government.

During the wild and lawless periods which immediately succeeded the subversion of the Roman empire, the proprietors of land, (that is, the nobility,) seem generally to have lived in fortified castles on their own estates, in the midst of their tenants and retainers. Many other individuals, too weak, singly, to defend themselves against the restless and rapacious spirit of the feudal chiefs and their dependants, sought protection from the caprice and violence of their more powerful oppressors, by combining together, and inhabiting within the precincts of some fortified place. There they industriously cultivated the useful arts and manufactures; and when united in such situations, were the more easily enabled to defend their persons and properties against the attacks of invaders. For some time, however, their political condition was but little different from that of the enslaved peasantry. They were, for the most part, obliged to court the protection or patronage of some powerful prince, nobleman, or ecclesiastic, near whose castle or residence they had established themselves; under whose clientship they accordingly stood, and to whom they were obliged to pay a considerable annual tribute, as the price of the protection which they enjoyed. Some conception may be formed of the degraded state in which the inhabitants of towns were then placed, from an enumeration of the privileges which were afterwards successively conferred upon them. The people, as Dr Smith observes, (*Wealth of Nations*, b. iii. ch. 3.) to whom it is granted as a privilege, that they might give away their own daughters in marriage without the

consent of their lord; that, upon their death, their own children, and not their lord, should succeed to their goods; and that they might dispose of their own effects by will; must, before these grants, have been either altogether, or very nearly in the same state of villanage with the occupiers of land in the country.

There were other analogous causes which also contributed to the increase of towns, during the dark ages. In those turbulent times, when law and government were only respected, in so far as they were seconded by the immediate application of constraining force, the princes of Europe found it extremely difficult to protect their remote subjects, and particularly those who inhabited the frontier provinces. On this account, they found it necessary to encourage the formation of towns, which should at once serve as a protection against domestic disturbances, and as a bulwark against foreign invasion. In Germany, for instance, in addition to the towns which already existed, the Emperor Henry I. founded several others in Saxony, Thuringia, &c. which he caused to be fortified; and, at the same time, conferred upon the inhabitants several important privileges. The same policy was pursued by his successors, and their example was imitated by the nobility. In England, even the principal cities appear, by Domesday-book, to have been, at the time of the conquest, little better than villages: but under the first princes of the Norman line, the towns and boroughs gradually rose to importance; and in the reign of King Henry II. they were so highly privileged, that if a bondman or servant remained in a borough a year and a day, such residence entitled him to the rank of a freeman.

During the 12th and 13th centuries, a remarkable revolution took place, in regard to the condition of towns, which powerfully operated upon political government, throughout the whole of Europe. This slow and silent revolution was partly a natural consequence of the riches acquired by the inhabitants of towns, by their application to industry and commerce, and was also partly owing to a new line of policy which the princes of Europe found it expedient to adopt. They had, at first, endeavoured to make use of the influence of the clergy, in order to repress the overgrown and formidable power of the nobility; but having, at length, gradually lost the greater part of their authority over the church, they were forced to look round for some other means of diminishing the weight of their powerful vassals. Such a counterbalance naturally presented itself in the increasing wealth and importance of the towns, and accordingly we find, that during the period above mentioned, the inhabitants of towns began, by degrees, to emerge out of that state of dependence and degradation in which they had hitherto existed, and at length to exert an influence on the affairs of government. Some of them asserted their independence by main force, others obtained it from their needy lords in consideration of a sum of money, and all were desirous of securing it by royal charters. This revolution in the political state of the towns began in Italy at the commencement of the 11th century. In France, Louis the Fat, who commenced his reign in 1108, was the first of the French kings who granted corporate privileges to the towns of his demesnes, either from views of political expediency, or from more mercenary motives; and his subjects followed his example. The greater part of these charters are of the 12th or beginning of the 13th century. The reader will find a long list of them in Du Cange's Glossary, v. *Commune*.

In Germany, the emperor Henry V. was the first who adopted this line of policy; and the measures which he and his successors pursued, gave rise to that powerful body of towns, which, as long as the German constitution remained entire, formed a distinct college or chamber at the imperial diet. The enjoyment of liberty and security gave a spur to the industry of the towns, and their population increased with their wealth. These communities had now an independent political existence, and were at length admitted to bear a part in the national councils. The example was given by England during the reign of Henry III. It was followed by France in the reign of Philip the Fair; and by Germany under the emperor Henry VII. But in no country has this system been pursued to such extent, or attended with such salutary practical effects, as in England.

It has been a question acrimoniously disputed, among our learned antiquaries, at what period the representatives of boroughs were first called to take a share in the national councils. Some have endeavoured to trace their origin as far back as the Saxon *Wittenagemote*: Others, on the contrary, have maintained, that the commons formed no part of the great council, till some time after the conquest. This controversy we are certainly inclined to consider as more curious than important. If the system of popular representation be of great antiquity, and if it be in itself salutary and expedient, it really appears to us to be a matter of very little consequence, whether its origin is to be dated from a more barbarous, or from a more civilized age. At the same time, we conceive it to be our duty to present our readers with a summary of the arguments by which the advocates of either side of the question have endeavoured to support and illustrate their opinions. Those who are desirous of enquiring more minutely into the merits of this controversy, may consult the volumes to which we refer them at the end of this article.

The advocates of the higher antiquity of the commons maintain, that their origin is to be traced to the original customs of the ancient German nations, among whom, according to Tacitus, (*de Mor. Germ.* c. 25.) all the freeholders enjoyed an equal right with the nobles to assist in important deliberations. This right they exercised, upon their first settlement in foreign countries, by assembling together in open plains; and this is asserted to have been the practice among the Anglo Saxons, the meadow near Staines, in which king John granted the great charter, being called *Runcme d*, or the *Meadow of Council*, because in ancient times it had been usual to meet there, and consult upon business which concerned the peace of the kingdom. This custom, it is said, had gone into disuse under, and even previous to, the Norman government; and the meeting in the reign of king John is the only instance of its having been revived. From a record cited by Dr Brady, so late as the fifteenth year of king John, it appears, that not only the greater barons, but all the inferior tenants in chief of the crown, had a right to be summoned to Parliament by particular writs; from which it is concluded, that till then, they had attended the great councils of the nation personally, and not by representatives. But these did not constitute all the freeholders of the kingdom; for this description comprehended all who held of the barons, either by knight service, or free soccage, all the possessors of allodial estates, and all the free inhabitants of cities and boroughs not holding of the crown. Was that numerous class of men altogether

excluded from Parliament, or were they present by any kind of representation? It has been supposed by some learned writers, that every superior tenant of the crown gave an opinion on matters of government, which bound all his vassals. But in this case, the allodial proprietors could not have been represented, nor, consequently, bound by the acts of the barons, to whom they were not attached by any feudal tie. Upon the above hypothesis, too, the right of the barons to sit in Parliament arose wholly from their tenures, and not from any trust conferred upon them by the people. It is certain, however, that the feudal superiority was the same under the government of Henry III. as under that of William the Conqueror. If, therefore, the barons, and superior holders of great fiefs of the crown, had, by virtue of the institutions of William I. been supposed to represent their vassals in Parliament, and the notion then was, that every inferior feudatory was bound by the parliamentary acts of his lord; how came that notion to be discarded in the 49th year of Henry III., to which period this change has been referred. An existing record, it is said, demonstrates this date to be false. A writ of summons, directed to the sheriffs of Bedfordshire and Buckinghamshire, and requiring two knights to be sent for each of these counties, is extant, in the close roll of the 38th year of Henry III. And there is also a clause in the great charter of the 9th of the same king, whereby it is declared, that, together with the spiritual and temporal lords, other inferior freeholders, *et omnes de regno*, by which, it is alleged, we are to understand, "the whole commonalty of the realm," granted to the king the fifteenth part of all their moveable goods, in return for the liberties acceded to them in that charter. We have no reason, it is observed, to presume, that so great an alteration was then first made in the constitution of England. Such an innovation must have produced disputes, which would have been noticed by some of the numerous historians of that age. But the English history is altogether silent as to any disputes between the nobility and the people, on this account, from the earliest periods of the Saxon government down to the reign of Charles I. Hence it is concluded, that the right of the commons must have been incontestably established by custom, and interwoven into the original frame of our constitution. Again: If we suppose, with some, that the sitting in Parliament was at that time considered only as a trouble and burden; the imposition of such a burden on orders of men, who had been previously exempt from it, must have been on their part resisted and opposed. But from the words of the act of the 4th Edw. III. by which "It is accorded, that a parliament shall be holden every year once, and more often, if need be," it may be inferred, that it was rather regarded as a privilege of which they earnestly desired the frequent enjoyment, than as a burden from which they wished to be exempt. There were some boroughs, indeed, which, on account of their poverty, were unable to bear the expense of sending members to Parliament, and therefore declined the exercise of that privilege; but it were unfair to form any general conclusion from these particular instances. Besides, there are examples of boroughs petitioning to be restored to the use of the privilege of sending members to Parliament, after a very long interruption.

It appears incredible, that, if the whole legislative power had, before the reign of Henry III. been always placed in the hands of the nobility and the king, they

should not have opposed the extension of it to so many persons of inferior rank; nor is it probable, that any new measure of such magnitude and importance, introduced by the earl of Leicester, while acting at the head of the nobles and the people in a very dangerous contest against the crown, should have been confirmed and perpetuated by Edward I. But among the close rolls of the 24th of that king, there is a writ of summons to Parliament, in which it is asserted, not as an innovation introduced by the earl of Leicester, "but as a maxim grounded on a most equitable law, established by the foresight and wisdom of sacred princes, that what concerns all, should be done with the approbation of all; and that dangers to the whole community should be obviated by remedies provided by the whole community;" a species of language which could not, with propriety, have been used by Edward I. if the practice of summoning the commons to Parliament had been a measure of recent introduction. It is, moreover, observed, that there is not the slightest intimation, in any of the oldest writs for sending up representatives from cities or boroughs, that such elections were a novelty. Two claims are still extant, made in the reigns of Edward II. and III. which have been held forth as decisive of the antiquity of the custom of sending citizens and burgesses to Parliament, even from towns that were held under subjects, and not immediately of the crown. These are the claims of the towns of St Albans and Barnstaple. In the petition of the borough of St Albans, presented to Parliament in the reign of Edward II. the petitioners assert, that though they held *in capite* of the crown, and owed only for all other service their attendance in Parliament, yet the sheriff had omitted them in his writs; whereas, both in the reign of the king's father, and all his predecessors, they had always sent members. This expression, it is alleged, could not have been used, if the commencement of the House of Commons were to be dated only from the reign of Henry III. Reference is also made to a statute of the 5th year of Richard II. st. 2. which enacts, "that all and singular persons and commonalties, which from henceforth shall have the summons of the Parliament, shall come from henceforth to the Parliaments in the manner as they are bound to do, and have been accustomed within the realm of England, of old times. And if any person of the same realm, which from henceforth shall have the said summons (be he archbishop, bishop, abbot, prior, duke, earl, baron, banneret, knight of the shire, citizen of city, burgesse of borough, or other singular person or commonalty,) do absent himself, &c. he shall be amerced and otherwise punished, according as of old times hath been used to be done within the said realm in the said case." There is likewise a petition of the Commons in the second Parliament of Henry V. which sets forth, "that as it hath ever been their libertie and freedom, that there should no statute nor law be made, unless they passed thereto their assent, considering that the commune of your land, the which is and ever hath been a member of your Parliament, be as well assenters as petitioners." &c. This claim was not disallowed either by the lords or the king.

Such is the general train of reasoning by which the advocates of the antiquity of the House of Commons have endeavoured to support their cause. They maintain that the people, that is the citizens and burgesses, always formed a constituent part of the great council; that the statutes and records to which they refer, are to be considered as merely sanctioning and confirming an

ancient privilege, and not as introducing any new measure of policy; and that although in some periods, and in certain instances, the people seem to have for a time discontinued the exercise of this privilege, yet that this discontinuance has been owing to particular circumstances, and ought not to have any effect upon the general argument.

Those, on the other hand, who deny this high antiquity of the commons, contend, and, we think, successfully, that in those periods to which their origin is referred, no such class of men as are denominated citizens and burgesses had any political existence. Although Tacitus affirms, that, among the ancient Germans, the consent of all the members of the community was required in every important deliberation; yet he speaks not of representatives; and this ancient practice, mentioned by the Roman historian, could only have place among small tribes, where every citizen might, without inconvenience, be assembled upon any extraordinary emergency. With regard to the Saxon Wittenagemote, it has not been determined with any degree of certainty by antiquaries, who were its constituent members. Besides the prelates and aldermen, or nobles, mention is also made of the *wites*, or wise men, as a component part of this national council; but who these wites were, it is not easy to ascertain from a review of the laws and history of that period. Some have supposed that they were the judges, or men learned in the law; others, that they were the representatives of boroughs, or what we now call the Commons. This latter supposition, however, appears to be contradicted by the expressions employed by all ancient historians, in mentioning the Wittenagemote. The members are almost always called the *principes, satrapæ, optimates, magnates, proceres*; which terms seem to apply only to an aristocracy, and to exclude the commons. Besides, the boroughs, from the low state of commerce, were, in those times, so small and so poor, and the inhabitants lived in such a state of dependence upon the feudal nobility, that it does not appear at all probable they would be admitted as a part of the national councils. We have already seen how slowly they emerged from this dependent state; and how gradually they acquired those privileges which entitle them to the rank of free men, and enabled them to exert an influence on the affairs of government. It may be remarked, too, that the commons are well known to have had no share in the governments established by the Franks, Burgundians, and other northern nations; and it is by no means probable, that the Saxons, who remained longer barbarous and uncivilized than those other tribes, could have ever thought of conferring such an honourable privilege on trade and industry. Indeed, in those rude ages, all who could boast the rank of free men were soldiers, and therefore the military profession was alone considered as honourable. The arts of industry were held in little repute, and were chiefly cultivated by persons in a servile condition. Even at the period of the conquest, as appears from Domesday-book, the greatest boroughs were scarcely more than country villages; and the inhabitants were of a station little better than servile. These boroughs were not then so much as incorporated; they formed no community; they were not regarded as a body politic; and being merely formed of a number of low, dependent mechanics, living in neighbourhood together, without any particular civil tie, they were incapable of being represented in the states of the kingdom. The first corporation, even in

France, which made more early advances in arts and civilization than England, is sixty years posterior to the conquest; and in Normandy, the constitution of which was most likely to be William's model in raising his new fabric of English government, the states were entirely composed of the clergy and nobility; and the first incorporated boroughs, or communities, of that duchy, were Rouen and Falaise, which enjoyed their privileges by a grant of Philip Augustus, in the year 1207. The famous charter, as it is called, of the conqueror, to the city of London, although granted at a time when he assumed the appearance of gentleness and lenity, is nothing but a letter of protection, and a declaration that the citizens should not be treated as slaves.

It is remarkable, that all the English historians, when they mention the great council of the nation, call it an assembly of the baronage, nobility, or great men; and none of their expressions can, without the utmost violence, be tortured to a meaning, which will admit the commons to be constituent members of that body. If, in the long period of two hundred years, which elapsed between the conquest and the latter end of the reign of Henry III., and which abounded in factions, revolutions, and convulsions of all kinds, the House of Commons never performed one single legislative act, so considerable as to be once mentioned by any of the numerous historians of that age, they must have been totally insignificant; and what reason, then, can be assigned for their ever being assembled? Every page of the subsequent histories discovers their existence; yet these histories are not written with greater accuracy than the preceding ones, and indeed scarcely equal them in that particular. The *Magna Charta* of King John, enumerates the persons entitled to a seat in the great council, viz. the prelates and immediate tenants of the crown, without any mention of the commons: an authority, as Mr Hume observes, so full, certain, and explicit, that nothing but the zeal of party could ever have procured credit to any contrary hypothesis.

The statutes and records, upon which the arguments on the other side of the question are founded, are chiefly of dates posterior to the period, when the commons are admitted, upon all hands, to have formed a part of the parliaments; and besides, they advance merely general principles and maxims of government, without any reference to particular facts. With regard to the claims of St Albans and Barnstaple, Mr Madox has shewn, that no such tenure was known in England, as that of holding by attendance in parliament, instead of all other service; and that, moreover, the borough of St Albans never held of the crown at all, but was always demesne land of the abbot. It is no wonder, therefore, says Mr Hume, that a petition, which advances two falsehoods, should contain one historical mistake, which, indeed, amounts only to an inaccurate and exaggerated expression; no strange matter in ignorant burgesses of that age, who wanted to shake off the authority of their abbot, and to hold of the king, without rendering any services even to the crown.

The first notice which is given by historians of any representatives being sent to parliament by the boroughs, occurs during the reign of Henry III. in the year 1265;—at the period when the Earl of Leicester had usurped the royal authority, and summoned a new parliament to London, where he knew his power was uncontrollable. This assembly he fixed upon a more democratical basis, than any which had been called together, since the foun-

datation of the monarchy. Besides the barons of his own party, and several ecclesiastics, who were not immediate tenants of the crown, he ordered returns to be made of two knights from each shire, and, what is more remarkable, of deputies from the boroughs; being the first time that this order of men appear to have been summoned to parliament. This period, accordingly, is commonly considered as the epoch of the House of Commons in England. The precedent, however, appears to have been regarded as the act of a violent usurpation, and to have been discontinued in subsequent parliaments, until the 23d year of Edward I., who, in consequence of his pecuniary embarrassments, occasioned by his foreign and domestic military expeditions, again had recourse to the measure of summoning the representatives of the boroughs to parliament; and this period seems to be the real and true epoch of the House of Commons, and the dawn of popular government.

At first, these representatives of boroughs did not, properly speaking, compose any essential part of the parliament: they sat apart both from the barons and knights, who appear to have regarded them as personages of a very inferior rank. Having given their consent to the taxes required of them, their business was considered as finished, and they separated, even although the parliament still continued to sit, and to canvass the national business. By this union, however, they gradually acquired more weight; and it became customary for them, in return for the supplies which they granted, to prefer petitions to the king for redress of any grievances of which they found reason to complain. The commons, however, do not yet appear to have assumed the character of legislators. Throughout the reign of Edward I., their assent is not once expressed in any of the enacting clauses, nor in the ensuing reigns, until the 9th of Edw. III. nor in any of the enacting clauses of 16th Richard II. Nay, even so late as Henry VI., from the beginning till the 8th of his reign, the assent of the commons is not once expressed in any enacting clause. (See Ruffhead's edit. of the *Statutes*, preface, p. 7.) So little were they accustomed to transact public business, that they had no speaker till after the parliament 6th Edward III., and, in the opinion of most antiquaries, not till the first of Richard II. The burgesses did not even form the same house with the knights of shires. But as their wealth and consideration gradually increased, so did also their public importance; and, in the reign of Henry V., the commons required, that no laws should be framed merely upon their petitions, unless the statutes were worded by themselves, and had passed their house in the form of a bill. They were, at length, united in the same house with the knights of shires. This union, according to Mr Carte, who had carefully consulted the rolls of parliament, does not appear to have taken place until the 16th of Edward III. See Carte's *Hist.* vol. ii. p. 451.) Even this union, however, was not uninterrupted; for instances afterwards occur of the knights and burgesses acting separately.

Thus did the commons, or third estate of the kingdom, gradually acquire their present form and importance. It were unnecessary for us, at present, to trace any farther the progress of an institution, which, besides the inestimable benefit of securing the liberties of the subject, has contributed so much to the efficacy and stability of the British constitutional government, as we shall have oc-

casional to revert to this subject in the articles PARLIAMENT and WITTENAGEMOTE.

Boroughs are distinguished into those by charter or statute, and those by prescription or custom. The number of boroughs in England and Wales, including cities and cinque ports, which send members to parliament, is 215; some of which send one, others two representatives.

Burgesses were first admitted into the Scottish parliaments by Robert Bruce, in the year 1326; and in the preamble to the laws of Robert III. they are ranked among the constituent members of that assembly. By the articles of the union, the Scottish boroughs send fifteen representatives to the British parliament.

Brady's *Historical Treatise of Cities and Boroughs*. Petyt's *Right of the Commons*. Brady's *Answer to Petyt*. Tyrrel's *Appendix to his Hist. of England*. Robertson's *Hist. of Scotland*. (z)

BOROUGH, in the law of Scotland, signifies a corporate body, erected by charter of the sovereign, and consisting of the inhabitants of a certain district, with jurisdiction annexed to it. Boroughs hold either of the crown, or of a subject: hence they are distinguished into boroughs royal, and boroughs of regality or barony. All royal boroughs have power, by their charters, to choose annually such office-bearers or magistrates as are specified in the grant; generally a provost, bailies, dean of guild, treasurer, and common council, who are elected in terms of the set or constitution of the borough.

The magistrates of royal boroughs have as extensive a civil jurisdiction within the borough, as the sheriff in his territory. They are also empowered by special statute, 1644, c. 35. revived by 1663, c. 6. to value and sell ruinous houses, when the proprietors refuse to rebuild or repair them. Their criminal jurisdiction, anciently pretty extensive, is now confined to petty riots. They never had jurisdiction in blood-wits, with the exception of a few boroughs, to whom that special right was granted by charter. The magistrates of some boroughs are, by their charters, constituted justices of the peace within the bounds of their erection; and, since the union, the eldest magistrate of every royal borough is named, of course, in all the commissions of the peace. In all matters of police, the magistrates and town council must concur, as the full representatives of the community. In this capacity they enact by-laws, choose persons into offices which are in their gift, &c.; and they may not only proportion the public taxes among the inhabitants, but also impose taxations, for the utility of the borough, by their own authority, provided they have not only the consent of the magistrates and council, but of the special corporations burdened.

The *Convention of Royal Boroughs* is composed of deputies or commissioners, one from each borough, who were, as early as 1487, c. 3. authorised to meet yearly, to consider of the "welfare of merchandise, the good rule and statutes for the common profite of burrows, and to provide for remeid upon the skaith and injuries sustained within the burrowes." Their powers were confirmed and enlarged by many subsequent acts; and accordingly that body have been in the practice of meeting annually in Edinburgh, for the purpose of regulating the matters committed to their charge.

In boroughs of barony and regality, the right of electing magistrates is, by the charter, vested sometimes in the inhabitants themselves, and sometimes in the baron or superior. Their jurisdiction extends to the cognisance of debts, and questions of possession between the inhabitants, and the superior's jurisdiction is always cumulative with that of the magistrates. See Erskine's *Inst. of the Law of Scotland*, b. i. tit. iv. § 20. Bell's *Dict. of the Law of Scotland*. (z)

BOROUGH-COURTS, are certain courts of private and special jurisdiction, held in different cities, boroughs and corporations, throughout the kingdom, by prescription, charter, or act of parliament. Of this species are the *Sheriff's Court*, and *Court of Hustings* in London. (z)

BOROUGH-ENGLISH, so called in contradistinction, as it were, to the Norman customs, is a customary descent of some tenements held in ancient burgage, and copyhold manners, in consequence of which the youngest son, and not the eldest, succeeds on the death of his father; and if the proprietor leaves no issue, the estate descends to his younger brother. Various reasons have been assigned for this singular custom. Littelton (§ 211.) alleges it is because the youngest son, by reason of his tender age, is presumed to be more helpless than the rest of his brethren. Other authors have given a much stranger reason for this custom. It originated, they say, from the lords of certain lands having anciently the privilege of breaking the seventh commandment with their tenants' wives, on their wedding night; and therefore the tenement descended not to the eldest, but to the youngest son, who was more certainly the offspring of the tenant. The custom alluded to, however, never prevailed in England, although it appears to have obtained in Scotland, under the name of *mercheta*, or *marcheta*, until it was abolished by Malcolm III.

Blackstone, on the other hand, endeavours to trace the origin of this species of descent in a more rational way by deducing it from the practice of the Tartars, and other pastoral tribes; among whom, according to Father Du Halde, this custom of descent to the youngest son also prevails. The reason assigned for it is this, that among nations composed totally of shepherds and herdsmen, the elder sons, as soon as they are capable of leading a pastoral life, migrate from their father with a certain allotment of cattle, and go to seek a new habitation; while the youngest son, who remains last at home with the father, is naturally the heir of his house, the rest being already provided for. This custom of the elder son's separating from the father, is also to be found among other northern nations; and the species of descent, called Borough-English, where it prevails, may be presumed to be a remnant of that pastoral state of society, which Cæsar and Tacitus describe as obtaining among our British and German ancestors. See Blackstone's *Comment.* b. ii. ch. 6. Jacob's *Law Dict.* (z)

BOROUGH-HEAD, or **HEAD-BOROUGH**, called also, in some places, the *Borsholder*, or *Borough's calder*, *Tithing-man*, &c. was a magistrate annually appointed to preside over a tithing, according to the institution of Alfred. He was one of the principal inhabitants, and presumed to be the discreetest man in the town or tithing. These head-boroughs are now a species of petty constables. See **CONSTABLE**, and **TITHING**. (z)

BOROUGH-BREACH, or **BURGH-BRECHE**, (*Borgi fractura*), signifies a breach of the peace by the inhabi-

tants of a tithing, which was punishable by a fine imposed upon the community. *LL. Canut.* c. 55. (z)

BOROUGH-BRIDGE, a market town of England, in the west riding of Yorkshire, situated upon the river Eyle, over which there is a good stone bridge. In a field near the bridge there are three large stones of a huge size, and of the form of obelisks, standing upright in the ground. They are called the Devil's Arrows, and are supposed by some to be trophies raised by the Romans, while others imagine that they were placed there by the Britons. The highest stone is 22 feet, and 16 feet in circumference; the second is 21 feet high, and 17 feet round; and the third is 17 feet high, and 24 feet in circuit. There was formerly a fourth stone, but it was long ago demolished. Several Roman coins and antiquities have been found in the neighbourhood. The town carries on a considerable trade in hardware, which is the only manufacture it possesses. Number of houses 113. Population 680. See Gough's *Camden's Britannia*, and Pennant's *Tour from Alston Moor to Harrogate*, 1804. (j)

BORROMEAN ISLANDS, the name of two islands called *Isola Bella* and *Isola Madre*, situated in the most western bay of the Lago Maggiore, and deriving their general name from the family of Borromeo, to whom they belonged.

The Borromean islands have been described with the greatest enthusiasm by Bishop Burnet and by Keyser as among the finest places in the world. Keyser says, "that these islands can be compared to nothing more properly, than to pyramids of sweetmeats, ornamented with green festoons and flowers." Keyser has given a very minute description of these islands, of which we shall avail ourselves in our account of the Lago Maggiore. At present we shall content ourselves with laying before our readers the brief description of them given by Mr Coxe, who does not seem to be such an enthusiastic admirer of these artificial islands. "As the taste of mankind alters with the succession of years, I considered it only as a monument of expense and folly. Terrace rises above terrace in regular gradations, bordered with flower-pots, or gigantic statues of horses, gods, and goddesses. The whole is raised upon arches, and the soil has been brought from the shore to cover them. The palace is magnificent, and contains a profusion of marbles and paintings. The lower part of the house overhangs the lake on one side, where several apartments are furnished in the style of grottos; the floors, pillars, and walls, are inlaid with various coloured stones, marbles, and shells; the view and the coolness united make this part a delicious summer retreat. If any thing justly gives this island the appellation of enchanted, it is the prospect from the terrace. The gradual diminution of the mountains, from the regions of eternal snow to the rich plain; the sinuosity of the lake; its varied banks; the bay of Marzozzo, bounded by vast hills; the neighbouring burgh of Palanza, and more distant view of Laveno; the numerous villages; the Isola Madre, on which is a palace of the Borromean family; and another island, sprinkled with fishermen's huts, form a delightful assemblage. These islands, and the whole western coast of the lake to the village of Locarno, was ceded to the king of Sardinia by the late empress queen at the treaty of Worms, in consideration of the assistance which she received from that monarch." See Coxe's *Travels in Switzerland*, vol. iii. lett. 91. p. 512. Burnet's *Letters in Switzerland*, 8vo. 1686, which

is also published in Harris's *Collection of Voyages*, vol. ii.; and Keyser's *Travels*, vol. i. lett. 35. p. 374, &c. (j)

BORROMEO, CHARLES, a celebrated cardinal of the Romish church, whose piety and zeal for reformation, entitle him to the remembrance of posterity. He was born at the castle of Arona, upon the Lago Maggiore, in October 1538, and was the son of Gilbert Borromeo, count of Arona, and of Mary de Medicis. At the early age of twelve, he was appointed to an abbacy, which had been hereditary in the family; but he accepted of this office merely that he might apply the revenue which it yielded to charitable purposes; and he afterwards refused to hold any new benefice, unless he was permitted to apply the income which it afforded to some benevolent or public use. After acquiring a knowledge of languages at Milan, and studying the canon and civil law at Pavia, he took his doctor's degree in 1559. In the following year, his uncle Pius IV. succeeded to the pontificate, and the highest prospects of preferment were thus laid open to Borromeo. He was invested with the dignities of cardinal nephew, archbishop of Milan, legate of Ancona, Bologna, Romagna, and protector of several crowns and religious orders. Elevated to such dignities at an early period of life, and necessarily surrounded with a brilliant train of attendants, we could scarcely have expected any of that humility and temperance with which Borromeo was distinguished. The first use which he made of the high influence he possessed, was to institute an academy, composed both of laymen and ecclesiastics, for the purpose of discussing literary topics, but particularly those which related to sacred subjects. This society met in the Vatican, and hence the transactions which they published were entitled *Noctes Vaticanæ*.

After the council of Trent had issued its decrees for the reformation of the clergy, Borromeo devoted himself, with the utmost ardour, to carry into effect these important resolutions. He dismissed at once 80 of his domestics; he abandoned the use of silk in his dress; and he began to reform the clergy, by increasing the means of their education. With this view, he founded a college at Pavia, and a Jesuit's college at Milan, and he took a principal part in erecting a splendid building for the university of Bologna.

Though strongly attached to the church of Rome, he was by no means blind to the vices and corruptions which were undermining its foundation, and he set himself to carry through a system of reform, perhaps too extensive for the power and influence of a single individual.

He revived the pastoral visits in Rome; he gave decency to public worship, by a number of salutary regulations; he cleared the cathedrals of those pompous busts and ornaments with which they were disfigured; and he began this unpopular work, by removing the monuments of his nearest relations.

This system was soon extended from the cathedrals to the other churches, to the fraternities of penitents, and even to the monasteries themselves, those fertile sources of every species of iniquity. In these salutary attempts he met with the most formidable opposition, which nothing but the most inflexible integrity could have surmounted. Even the civil power began to re-

gard such changes with a jealous eye, and, contrary to its strongest interests, to retard, by remonstrances and complaints, the completion of Borromeo's plans. This opposition, however, was not so overpowering as that which he met with from several of the religious orders. Three provosts of the order of the Brothers of Humility, conspired against the life of the cardinal, and one of their confederates undertook the execution of their dark design. While Borromeo was performing his evening devotions in the archiepiscopal chapel of Milan, the assassin fired a harquebuss at him, but he fortunately missed his aim, and the life of the venerable cardinal was preserved.

The plague, which visited Milan in the year 1576, afforded a grand opportunity for the display of those great virtues which distinguished Borromeo. In procuring accommodation for the sick, in burying the dead, and in making regulations for keeping contagion from those that were healthy, the good cardinal exposed himself to every danger, and even sold his goods in order to procure the means of relieving the distress of his people.*

Worn out with these labours, and by that abstemious severity which he prescribed to himself, Borromeo was seized with an intermittent fever while at a place called the Sepulchre, on the mountain Varais. The violence of the disease permitted him, with difficulty, to travel to Milan, where he expired the day after his arrival, on the 4th of November 1584, in the 47th year of his age.

The sensations of true sorrow which were felt for the loss of this great man, extended beyond his own diocese to every corner of the province. He was immediately worshipped as a saint by the vulgar, though he was not regularly canonized till the year 1610.

At a little distance from the town of Arona, towards the Borromeian islands, a colossal statue of brass has been erected in honor of Borromeo. It is placed on an eminence, very near a seminary for forty boys, founded by the cardinal. It is about 35 ells high,† and stands upon a pedestal about 25 ells in height. Borromeo is represented in the cardinal's habit, looking towards Milan: he has a book under his left arm, and his right hand is extended, as if he were in the attitude of blessing the city. This statue was cast at Milan, and was brought to Arona in separate pieces. Keyser, however, says, that it consists of one single piece.

The writings of Borromeo were very numerous, and were collected in 5 vols. folio, and printed at Milan in 1747. His *Acta Ecclesie Mediolanensis* was published in folio, in 1519. A life of Borromeo was published in the 17th century by Ribadeera, a Spanish Jesuit, which is filled with ridiculous fables respecting the miracles of the cardinal. Another life of him was published at Paris in 1761, in 3 vols. 12mo., by the Abbé Tournon. See Keyser's *Travels*, vol. i. let. xxxv. p. 373; and Coxe's *Travels in Switzerland*, vol. iii. let. xci. p. 314.

(a) **BORROWDALE**. See CUMBERLAND.

BORROWSTONNESS, a town of Scotland, is situated on the south side of the Firth of Forth, about 18 miles north-west of Edinburgh, and 3½ north of Linlithgow, the county town. At what time the town of Borrowstonness began to be built is not exactly known, but it be-

* The exertions of Borromeo during the prevalence of the plague, form the subject of many of the finest pictures of Milan.

† Mr Coxe says, that the height of this statue is 60 feet.

came a place of some consequence early in the seventeenth century; for in the year 1634 the population had increased so much, that an application was made to the parliament of Scotland to have the town erected into a separate parish from Kinnell, of which it had hitherto formed a part. And in the year 1669, the then duke and duchess of Hamilton applied for, and obtained an act of parliament, conjoining Kinnell to Borrowstoness; since which period they have continued one parish.

The town is a burgh of barony governed by a baron bailie, appointed by the Hamilton family; and although it is built in a very irregular manner, there are a number of good dwelling-houses, besides several very large and commodious warehouses for grain, &c. The two principal streets are narrow, and run from west to east about 350 yards, when they terminate in one, which is continued nearly 500 yards farther. The houses, from the smoke of the public works carried on in the town, bear all the marks of antiquity, and strangers are struck with the pandemonian appearance of the place. The smoke, however, is by no means so offensive as might be supposed, and, to those accustomed to it, seldom gives any concern,—at any rate it is not pernicious to the health of the inhabitants, there having been many instances of longevity; and at present there are several persons living above 80 years of age, and, in particular, one lady, said to be 94, who continues vigorous and in good spirits.

The town stands upon a point of land projecting into the sea, and nature seems to have pointed it out as an advantageous situation for a harbour. Previous to the existence of Borrowstoness, and for many years after it began to be formed, Blackness (a small village about 3 miles east of Borrowstoness,) was the place where the Glasgow merchants carried on the principal part of their trade with the east country; but Borrowstoness being nearer, and in every respect better adapted for the purpose, the shipping soon began to resort there. As a consequence of this, about the time of the union, in 1707, the customhouse appears to have been transferred from Blackness to Borrowstoness, where it still remains. Commerce continued to be carried on at Borrowstoness to a considerable extent, more particularly betwixt the years 1750 and 1780, during which period it was one of the most thriving towns on the east coast, and ranked as the *third* port in Scotland. But when the junction of the Forth and Clyde took place about 30 years ago, by means of the great canal, the trade began to resort to Grangemouth, (at that time called Lealeek,) where the canal terminates on the east; and the trade of Borrowstoness has since continued to decline. The merchants and others interested in the prosperity of Borrowstoness, soon foresaw the injury it would suffer by being deprived of the Glasgow trade, and with the view of obviating it, a subscription was opened in 1782, and an act of parliament obtained for making a branch from Borrowstoness to join the great canal at or near Grangemouth, which was actually begun and carried some length, but the funds failing, it was necessarily stopped, and still remains unfinished. The completion of this undertaking was the only probable means of preserving the trade at Borrowstoness, the harbour there being much more accessible to ships of size than Grangemouth, where the navigation is both very narrow and crooked; but it having unfortunately failed as above stated, Grangemouth has become the

seat of commerce. All the customhouse business, however, being transacted at Borrowstoness, the town continued to derive some advantages from the resort of merchants and shipmasters, &c.; but of this advantage it has also been lately deprived, Grangemouth having been constituted a separate port, and a new customhouse opened there on the 1st Dec. 1810.

From the causes which have been stated, and more recently from the pressure of the war, the trade of Borrowstoness has become small indeed, compared to what it once was.

The following table exhibits the quantity of shipping employed in the foreign and coast trade, inwards and outwards for four years preceding the 5th January 1811, with the nature of the trade carried on.

Year ending	Inwards.				Nature of the Trade
	Foreign Trade.		Coast Trade.		
	Ships.	Tons.	Ships.	Tons.	
Jan. 5, 1806	20	2615	151	7069	} Timber, deals, iron, blubber, and furs. } Flax, madder, and grain.
1809.	4	917	113	5904	
1810.	4	906	122	6019	
1811.	8	1399	150	6083	

Year ending	Outwards.				
	Ships.	Tons.	Ships.	Tons.	
Jan. 5, 1806.	8	1301	168	6625	} Coals, salt, soap, soapers } salt Provisions, grain, } and stone and earthen } ware.
1809.	3	775	184	8472	
1810.	8	1332	207	8863	
1811.	6	1196	203	8367	

The above view of the trade shows how limited the foreign commerce has become, and that the imports have fallen off considerably ever since the year 1806.

The shipping of Borrowstoness has also much decreased since 1794. At that time there were seventeen brigs and eight sloops belonging to the town, but now they cannot be reckoned above half that number. The building of ships, however, is still carried on, although not so extensively as formerly. There is only now one master builder, whose mode of building is held in high estimation, and his vessels consequently meet with a ready market.

Several branches of manufacture and mechanical industry are carried on in Borrowstoness. Of these, the making of salt deserves first to be mentioned. This useful manufacture is carried on to a great extent here and in the neighbouring village of Grangepans. It is a lucrative concern to the proprietors, and produces a considerable revenue to the crown.

A pottery for manufacturing stone and earthen ware was begun in the year 1784, and is still continued upon a pretty extensive plan. This branch of business, however, is at present suffering, in common with others, under the pressure of the times. In the year 1803 an English gentleman, who has devoted his attention to chemical studies, settled in Borrowstoness, and carries on with considerable success, the making of *sal ammoniac*.

The manufacturing of *soap* is likewise a branch of industry in the place. There is also, in the immediate neighbourhood, a distillery newly erected, upon a pretty large scale, and at considerable expense.

And at present, two capacious lime kilns are building at the west end of the town, for supplying the farmers in the neighbourhood with lime for their land. The stones are brought by sea from Dunbar; and the coal for burning them is got, at a reasonable rate, from the duke of Hamilton's coal works.

Many of the women in the town and country around, are employed in tambouring, and in the spinning of silk sent from London to agents here, who return the yarn to be manufactured into stockings.

Two of the Leith whaie ships have fitted out here for some years past, and return with their blubber, which is manufactured into oil at a boiling house a little above the town.

As a natural consequence of the decay of trade, a number of families have from time to time left the place; and, at present, there are several good houses, besides some of an inferior sort, without inhabitants.

In these circumstances, it is not surprising that the population since the year 1794, should have diminished above 400.

At that time it was 2613

But at present (1811) it does not exceed, 2200

From the facts which have been mentioned, it appears that this place is in a very declining state. It is indeed hardly possible to conceive that the foreign trade and shipping can be less than they are. It is more probable, were peace restored and a communication opened with the great canal, (as formerly unsuccessfully attempted,) Borrowstoness, from its advantageous situation and excellent harbour, might still revive, and even surpass what it was at the time of its greatest prosperity. (r. n.)

BORYTHENES. See DNIEPER.

BOSCAWEN'S ISLAND, or **KOOTAHE,** the name of an island in the South Pacific ocean, discovered by Schouten and Le Maire in 1616. It is about three miles in diameter, and is lofty and of a conical form. It is populous and productive, and is situated in W. Long. 173° 48', S. Lat. 15° 55'. See Introduction to the *Missionary Voyage*, p. 67. (j)

BOSCIA, a genus of plants of the class Tetandria, and order Trigynia. See BOTANY.—The same name has been given by La Marck to another genus of the class Dodecandria, and order Monogynia. (w)

BOSCOVICH, ROGER JOSEPH, a celebrated mathematician and natural philosopher, was born at Ragusa, a city of Dalmatia, and capital of the little republic of the same name, on the 11th of May, 1711. His father, who was a respectable citizen of Ragusa, had no fewer than nine children, of whom Joseph was the youngest. At an early age he was sent to learn grammar and philosophy at the schools of the Jesuits in Ragusa. The temper and abilities which he displayed in the course of his education, pointed him out as a young man who might one day do honour to that able and enterprising association. Influenced, perhaps, by the example of his brother, who had entered the church, Boscovich applied for admission into the order of the Jesuits; and in the fifteenth year of his age, he went to Rome and took the habit of the novice. In this new situation, his attention was principally directed to the constitution of the order, to the study of rhetoric and belles lettres, but particularly to the composition of Latin poetry, in which he afterwards obtained such distinguished eminence. Having completed these preliminary studies, Boscovich was sent to the Jesuits college at Rome to study mathematics and

philosophy. These new branches of knowledge gradually gained upon his affections, till he found himself completely absorbed in the study of the sciences. With a rapidity, unusual even in the history of genius, he made himself master of all the branches of elementary geometry; and when his preceptors were no longer able to assist him in his daring flight, he prosecuted without any help, the higher geometry, till he was enabled to read the *Principia* of Newton. In consequence of the reputation for mathematical knowledge which he thus acquired, he was employed to give private lessons in that science, and was exempted from the drudgery of teaching grammar and the classics, which all the noviciates of the order were obliged to undergo for five years before they were admitted to the study of theology. From the humble station of a private teacher, Boscovich was promoted to the professorship of mathematics at Rome, a situation for which he was eminently qualified, from his acquaintance with the works of the ancient geometers, as well as from the happy talent which he possessed for communicating his ideas to others. He was now led, by the nature of his duties, to compose elementary treatises on arithmetic, algebra, geometry, trigonometry, and conic sections, a task which he executed with an ability and success which men of genius seldom display in elementary compositions. His system of geometry contained the leading truths of that science in fourteen propositions; and his treatise on conic sections, which appeared in 1755, has been much admired for the simplicity and elegance of its demonstrations.

In the public disputations, the genius of Boscovich was principally called into action. His love of glory was highly inflamed by every accession to his fame; and he omitted no opportunity to gratify this favourite propensity, in the only way in which it ought to be gratified, by a zealous prosecution of philosophical discovery, and by an unremitting assiduity in promoting the happiness of his fellow creatures. Under the influence of such excitements, Boscovich directed his attention to almost every branch of physical science. A new theory of the solar spots; the transit of Mercury over the sun; the figure of the earth; the annual aberration of the fixed stars; the inequalities in terrestrial gravity; the limits of certainty in astronomical observations; the solid of greatest attraction; the comets; the flux and reflux of the sea; and the atmosphere of the moon, were among the subjects of astronomy which he investigated. In pure mathematics, he wrote upon osculating circles; on infinitesimals; on the cycloid; on logistic curve lines; and on the calculation of fractions. His optical dissertations were, on a new telescope for celestial objects; on light; on the rainbow; on lenses and dioptrical telescopes, and on the object glass micrometer. Besides these various papers, he wrote on the aurora borealis, on the motion of bodies in unresisting media, on the *vires vivæ*, on the centre of gravity, on the law of continuity, and on the divisibility of matter. In the course of these various investigations, the attention of Boscovich was necessarily drawn to the constitution of matter; and he appears, even at this early part of his life, to have formed an outline of that Theory of Natural Philosophy which has been so universally admired, and on which his reputation as a philosopher principally depends.

Nor was the attention of Boscovich confined to the physical and mathematical sciences. He had a wonder-

ful facility in the composition of Latin verses ; and such was his love for this species of amusement, that every incident, however trifling, called forth an offering to the muses. With such talents and acquirements, the company of Boscovich was assiduously courted at Rome ; and at every party to which he was invited, he shone, by the liveliness and fluency of his conversation. With a pardonable vanity, which is not usual with men of profound genius, he often led the conversation of the company to the subject of his own studies, which he had a singular faculty of explaining to the most common capacities ; and he seemed to derive particular pleasure from the recitation of long passages of his own poetry. This happy talent of amusing a company with subjects of science, though it may have been possessed by other philosophers, was certainly exhibited for the first time in the manners of Boscovich. The habits of abstract thought and close reasoning, which a natural philosopher must necessarily acquire, are utterly incompatible with that quickness of association and versatility of thought, which are the principal sources of extemporaneous declamation. These antisocial habits, however, are less hostile to his colloquial efforts, than the nature of the subjects with which the mind of the natural philosopher is principally conversant. While the study of history, poetry, and the belles lettres, furnish numerous and interesting topics of general conversation, the man of science is prevented from introducing subjects which would be generally unintelligible, and is thus denied the opportunity of displaying his knowledge and his talents, which is granted to those who cultivate literature and the fine arts. In what manner Boscovich overcame these difficulties, it is not easy to discover ; but he must have possessed no ordinary confidence in his talents, and no ordinary influence over the minds of others, who could fix the attention of a mixed company upon the abstract speculations of science and philosophy.

The fame which Boscovich now enjoyed was not confined within the limits of his native country. He was admitted, without solicitation, into most of the learned societies of Europe, and, without enjoying any of the substantial patronage of kings, he was honoured with their invitations and their praise. Pope Benedict XIV. consulted him on several subjects of civil engineering, and appointed him a member of a committee consisting of architects and mathematicians, who were assembled from different parts of Italy, to examine the cupola of St Peter's, in which a rent had been perceived. The architects and the mathematicians differed in their sentiments ; but the latter, with Boscovich and the Marquis Poleni at their head, finally prevailed. Boscovich proposed to strengthen the cupola by enclosing it in a circle of iron ; and this opinion being adopted, the Marquis reported it to the Pope, but unfortunately neglected to give Boscovich the merit of the suggestion. This omission grievously offended the vanity of the mathematician, and conspired, along with other causes of mortification, to make him resolve on quitting Rome. About this time, John V. of Portugal had determined to survey Brazil, and to fix the boundaries between that country and the territories belonging to Spain. He applied to the general of the Jesuits for ten mathematicians to execute this plan ; and no sooner did Boscovich hear of the project, than he offered to superintend the

undertaking, and to measure, at the same time, a degree of the meridian. The enlightened minister of Benedict XIV., unwilling that Italy should lose one of her greatest ornaments, appointed Boscovich to correct the maps of the papal territories, and to measure a degree of the meridian in Italy. Provided with excellent instruments, and assisted by Christopher Maire, an English Jesuit, Boscovich began the undertaking about the end of the year 1750 ; and after two years labour, he extended the meridian from Rome to Rimini, across the Apennine chain, and found that the length of a degree in the latitude of 43° was 56,979 toises. During the intervals of this active employment, he was engaged in completing his *Elements of Conic Sections* ; and when travelling over the mountains, he is said to have composed, on horse-back, his fine Latin poem, entitled, *De Solis ac Lunæ Defectibus*, "on the Eclipses of the Sun and Moon." An account of this survey was published by Boscovich at Rome and Paris, along with some excellent dissertations on several subjects connected with his undertaking. At the completion of a service so full of labour and anxiety, Boscovich was entitled to expect some adequate remuneration, or some office that would have freed him from the drudgery of teaching. The Pope, however, who seems to have undervalued the national work which he had just completed, presented him with a gold box, and the paltry sum of 100 sequins.* In consequence of this blind parsimony, Boscovich was compelled to resume the labours of his mathematical professorship.

A dispute respecting the draining of a lake, which, about this time, originated between the Tuscan government and the republic of Lucca, afforded a new opportunity for the exercise of Boscovich's talents. A number of mathematicians and commissioners had been appointed to decide the controversy ; but the commissioners having failed to appear, he repaired to Vienna to obtain the decision of Francis I. whose influence was paramount in Italy. At the Austrian capital he employed his poetical talents in celebrating the successes of Francis over Frederick the Great ; but his attention was chiefly directed to his new theory of natural philosophy, which he is said to have drawn up in the short space of thirty days, and which he published at Vienna in 1758, under the title of *Theoria Philosophiæ Naturalis redacta ad unicam legem virium in natura existentium*, a work of distinguished merit, which we shall have occasion to consider at great length in the subsequent article.

Having succeeded in settling the dispute in favour of the republic of Lucca, he was handsomely rewarded by the senate with a present of 1000 sequins.†

The talents of Boscovich as a negociator, pointed him out to the Senate of Ragusa, as the fittest person for settling a misunderstanding that existed between that republic and the British government. It was alleged by the latter, that the Ragusans had infringed their neutrality by fitting out vessels for the French service ; and as there had been no just ground for this suspicion, so injurious to the commerce of his native city, Boscovich repaired to London, and succeeded in establishing the integrity of the republic of Ragusa.

On his way to London, Boscovich visited Paris, where he remained for six months, enjoying the exquisite society which then distinguished the French metropolis.

* About forty-five pounds sterling.

† About four hundred and fifty pounds sterling.

During his stay at London, he was chosen a Fellow of the Royal Society in 1760; and he published his work, *De Solis ac Lunæ Defectibus*, which he dedicated to that learned body.

The approaching transit of Venus in 1761, had at this time absorbed the attention of philosophers, and numerous parties of astronomical observers were sent to different parts of the world. Boscovich was invited by the Royal Society to accompany the party of its members that was going to America; but as such an expedition would have greatly retarded his return to Italy, and interfered with some other plans, he was obliged to decline the invitation, and return to his native country. At Venice he met with his friend Corner, who accompanied him to the Plain of Troy, which they visited on their way to Constantinople. During his residence in Constantinople, his happiness was completely embittered by a continuance of ill health, which rose to such a height that it frequently threatened his existence. After he had begun to recover his strength, he left Constantinople in the train of the English ambassador, Sir James Porter, and travelled through Bulgaria, Moldavia, and part of Poland, with the intention of visiting the capital of Russia; but the death of Peter deterred him from the prosecution of his travels. An account of this journey was afterwards published in French and Italian, but it did not add much to the fame of its author.

The return of Boscovich to Rome was eagerly welcomed by his countrymen, and his talents were speedily called into exercise for the public good. In the spring of 1764, the Austrian governor of Milan appointed him to the mathematical chair in the university of Pavia, where the mean jealousy of his colleagues forced him to defend his reputation by the publication of his *Dissertationes Dioptricæ*, which related principally to the correction of the aberration of refrangibility in achromatic telescopes. The fame which he derived from this ingenious work, silenced, for a while, the calumnies of his rivals; but their malice having again broken out with increasing violence, Boscovich sought for tranquillity in a journey to France and the Netherlands. When he returned from this excursion, he was transferred from the college of Pavia to the Palatine schools at Milan, where he received from the Empress queen the professorship of astronomy and optics, and was also appointed to superintend the observatory of the Royal College of Brera, which was furnished with instruments chiefly at his own expense.

When Boscovich had repaired to the baths of Albano to strengthen his constitution, he received the mortifying intelligence, that several of the young Jesuits whom he had employed as assistants, had conspired against his favourite pupil, and had prevented the government from appointing him to some office of trust. He complained, in vain, to Prince Kaunitz and to the governor of Milan, of this insulting conduct; but having received no redress, he retired to Venice, where he continued for ten months, and at last formed the resolution of spending the remainder of his days at Ragusa. When he was upon the eve of carrying this resolution into effect, his plans were completely frustrated by the suppression of the order of Jesuits in 1773.

In consequence of this sudden revolution, so hostile to his temporal interests, he went to Paris along with

La Bord, the chamberlain of Louis XV., and sought in a foreign country those honourable rewards of genius which had been so unjustly denied him in his own. The influence of his friend La Bord procured for him the patronage of the French king, who appointed him Director of Optics for the Marine, a new office created on purpose, with two pensions, amounting to 8000 livres.* Such rapid promotion given to a foreigner, naturally excited the jealousy of the French philosophers. The piety of Boscovich, the freedom of his conversation, and his personal vanity, were by no means calculated for the meridian of Paris. The generosity of the sovereign was not seconded by the kindness of his subjects; and Boscovich, after all his services to science, was doomed to experience a neglect, which was the more mortifying, when he reflected on the idolatry with which he was formerly regarded at Rome. To a man of keen temper, like Boscovich, who knew his own merits, this cold treatment was unsufferable. He therefore requested leave of absence from his royal patron, and retired, in 1783, to Bassano, in the state of Venice, where he employed himself in preparing for the press a collection of his unpublished works, which he completed in 5 vols. 4to, entitled, *Rogeriü Josephi Boscovich, Opera selectissima ad Opticam et Astronomiam maxima ex parte Nova, et omnia hucusque inedita, in quinque tomos distributa*. Bassani, 1785.

Many of these dissertations are extremely valuable; and the mathematical investigations which they contain, are distinguished by a clearness and elementary simplicity which is very unusual in similar writings. When this labour was at an end, he spent some months in the convent of Valombrosa, in Tuscany, and afterwards went to Rome to revisit the companions of his early years. From Rome he went to Milan, where he resumed his own studies, and amused himself with completing a new edition of his friend Benedict Stay's beautiful poem, entitled, *Philosophia Recentior*, enriched with notes, and extended to ten books. The proposals, however, which he issued about this publication, did not obtain him many subscribers; and the limited circulation which his works experienced, excited a dejection of spirits which his constitution was not able to bear. His leave of absence from Paris was now nearly expired, and he felt the greatest reluctance to return among the jealousies which surrounded him in the French capital. The conflict between his gratitude to the French king, and his own personal feelings, increased the melancholy which preyed upon his spirits, while a violent attack of the gout, and an inflammation in the lungs, completed his sufferings, and drove him into a state of derangement.

Though this dreadful disorder proceeded, in some measure, from the bodily infirmities of Boscovich, yet it was chiefly owing to that secret anguish which sprung from the ingratitude of his countrymen, and the injustice of his cotemporaries. The visions of youthful ambition which the sanguine hopes of Boscovich had so early cherished; the reverence which was paid to him at Rome, at Paris, and at London; the great success of his writings; the high employments which he was afterwards called to fill, and the favour which was shewn to him by several of the princes of Europe,—the recollection of these better days, contributed to awaken more acute sensations at the neglect into which, in his old age, he had been permitted to fall. He felt that all his

* About three hundred and thirty-three pounds sterling.

philosophy was insufficient to quiet the ferment of a proud spirit, and he sought in religion for that support which it alone could bestow. Under the influence of these pious feelings, he regretted that he had spent so little time in the sacred duties of his profession, and that so much of his leisure had been occupied, by what he now considered, as the idle speculations of philosophy. We are unwilling to believe, with one of the biographers of Boscovich, that these religious impressions were the consequences of his mental delirium. At no period of his life, did Boscovich ever hazard an opinion hostile to the noble sentiments which supported him in his latter

days; and the reverses and disappointments which embittered the close of his life, naturally carried his views beyond this troubled state of existence, which a proud and mortified spirit is so willing to resign. Under the influence of these feelings, an imposthume burst in his breast, and he died on the 13th of February, 1787, in the 76th year of his age. He was interred without any kind of pomp, in the parish church of St Maria Pedore; and the Senate of his native city erected a monument to his memory, with the following inscription, composed by his friend Benedict Stay :

Boscovich was considerably above the middle size, of a strong make, and with a long and fallow visage. He possessed the virtues and the failings which spring from a warm temper; and while the former endeared him to his friends, the latter proved injurious only to himself. His numerous writings are evidently the production of an original and inventive genius, and though composed in a diffuse style, and with a redundancy of illustration, are distinguished by a simplicity and perspicuity which are seldom found in physical investigations.

The works of Boscovich which he published at Bassano, contain the following Opuscles :

VOL. I. Opusc. 1. De constructione et usu novi instrumenti maxime idonei ad determinandas vires refractivas, et distractivas substantiarum diaphanarum. Opusc. 2. Deductio formularum pertinentium ad focos lentium, cum earum applicatione ad calculandas sphaericitates, quæ adhibendi debent pro telescopiis acromaticis.

VOL. II. Opusc. 1. De correctionibus pertinentibus ad oculares, quibus accedit correctio solius erroris figuræ sphaericæ objectivorum. Opusc. 2. De Lente ustoria potissimum ingenti. Opusc. 3. De modo determinandi discrimen velocitatis, quam habet lumen, dum percurrit diversa media, per dua telescopia dioptrica, alterum commune, alterum novi cujusdam generis. Opusc. 4. De novo genere micrometri objectivi. Opusc. 5. De telescopis exhibenti simul binas imagines ejusdem objecti, alteram directam, alteram inversam, cum earum motibus contrariis et æqualibus. Opusc. 6. De globulis nigris translatis per discum solis, cum Epistola Gallica ad ejus phenomèni observatorem. Opusc. 7. De refractionibus astronomicis. Opusc. 8. De refractionibus astronomicis, et altitudine poli, determinandis per distantias apparentes binarum fixarum supra et infra polum. Opusc. 9. Methodus determinandi refractiones astronomicas sine ulla suppositione physica, quæ non videantur omnino certa, ope instrumenti habentis utilitatem generalem in tota astronomia.

VOL. III. Opusc. 1. De la determination de l'orbite d' une comete par trois observations pas eloignées entr'elles. Opusc. 2. Sur la nouvelle planete.

VOL. IV. Opusc. 1. De verificatione divisionum quadrantis muralis. De verificatione machinæ parallacticæ. Des formules differentielles de trigonometrie. De rhombo micrometrico.

VOL. V. Opusc. 1. De apparitione et disparitione annuli Saturni. Opusc. 2. Sur les elements de la rotation du soleil sur son axe determines par observations de ses taches. Opusc. 3. De determinatione longitudinis penduli oscillantis ad singula secunda temporis medii. Opusc. 4. Notice abregée de l'astronomie pour un marin. Opusc. 13. De calculando aberratione

astrorum orta e propagatione luminis successiva, &c. and several other opuscles on the orbits of the comets and planets.

The principal works published by Boscovich in a separate form, were,

De Maculis Solaribus exercitatio Astronomica, habitum Collegio Romano Soc. Jesu. Rom. 1736. 4to.

De Mercurii novissima intra solem transitu, dissertatio habita in Collegio Romano. Rom. 1737. 4to.

De Inequalitate gravitatis in diversis terræ locis, dissert. habita in Sem. Roman. Rom. 1741. 4to.

De Annis fixarum Aberrationibus. De Observationibus Astronomicis, et quo pertingat earumdem certitudo. Disquisitio in universam astronomiam. Rom. 1742. 4to.

De Motu Corporis attracti in centrum immobile, in spatiis non resistentibus. Rom. 1743. 4to. This is published in the Comment. Bonon. 1747. tom. ii. p. 111.

Nova Methodus adhibendi phasium observationes in eclipsibus lunaribus. Rom. 1744. 4to. This is also published in the Memoire sopra la fisica, &c. in Lucca per li Salani, 1747. 8vo.

De Cometis. Rom. 1746. 4to.

De Æstu Maris. Rom. 1746.

Dissertatio de Lumine. Rom. 1749. 4to.

Osservazioni dell' ultimo passaggio di Mercurio sotto il soli, reguito a' 6 di Maggio 1753. Rom. 1753.

De Lentibus et telescopiis dioptriciis. Rom. 1755. 4to.

De Inequalitatibus quas Saturnus et Jupiter sibi mutuo videntur inducere. Rom. 1756. This paper was drawn up for the prize given by the Academy of Sciences; but the Memoir of Euler was successful.

Philosophiæ Naturalis theoria redacta ad unicam legem virium in natura existentium. Viennæ, 1758. 4to. The second edition of this work appeared at Venice in 1762, and the third at Vienna in 1764.

De Solis ac Lunæ defectibus libri quinque. London, 1760, 4to. This work was reprinted at Venice in 1761 in 8vo.; and a French translation of it by the Abbé Baruel, appeared at Paris in 1779.

Voyage Astronomique et Geographique pour mesurer deux degrés du meridiem par les PP. Maire et Boscovich, traduit du Latin, par le P. Hugon, et augmenté par le P. Boscovich lui-même.

Memoire sulli cannocchiali diottrici. Milan, 1771.

Beside these works, Boscovich wrote several treatises on practical hydraulics, connected with the subject of rivers, harbours, and lakes. See *Elogio del Boscovich per il Sr. Baiamonti*.—Ragusa, 1789, 8vo. *Journal des Savans*, Feb. 1792, p. 113. *Journal de Paris*, 13th Mars. 1787. (β)

BOSCOVICH'S THEORY.

THE theory of natural philosophy which claims Boscovich for its author, has attracted, in no small degree, the attention of the learned: And although we are by no means disposed to imagine, that much progress is likely to be made in physical science by the original excogitation, or by the general application of theories of any kind, and are rather inclined to fall in with the opinion of the celebrated Bacon, that mankind are much more liable to be seduced into the winding mazes of error and fancy, than directed in the more difficult path of truth and knowledge, by that fondness for systems, and those habits of generalization, to which they are so much addicted; yet this theory has appeared so specious, so general in its application, and so well adapted to the explanation of most of the difficulties that occur in physical science, that we have thought it would be proper to give our readers such an account of it, at least, as, if not sufficient to render them masters of the ingenious conceptions of its author, may perhaps induce them to search for farther information, in the works of the illustrious Ragusan.

This theory is alleged, by Boscovich, to hold the mean between those of Leibnitz and of Newton; since it admits, with the former, that the elementary particles of matter are simple and unextended; and with the latter, that they act on each other by mutual forces, which are variable at different distances.

We may add too, that, with Leibnitz and his followers, Boscovich argues strenuously for the existence of the general law of continuity. While, with the followers of Newton, he admits, in general, the *actio e distantia*; and also agrees with them in their ideas respecting light, gravity, the pressure of fluids, &c.

But from the Leibnitzian this theory differs widely, in not admitting that continued extension can arise from contiguous and inextended atoms; a difficulty long ago urged against the system of Zeno; and also, in alleging, that the ultimate particles of matter are homogeneous, in opposition to the principles of *indiscernibles*, and the *sufficient reason* urged against that doctrine by the disciples of Leibnitz.

From Newton also he conceives himself to differ, in explaining by one law of forces, not only all those phenomena (and many more) for which the former author, in his last optical query, seems to think three principles were requisite, viz. gravitation, cohesion, and fermentation; but also in alleging, that, at the least distances, the mutual forces are not attractive, but repulsive; and that this repulsive force, with the diminution of distance, increases in *infinitum*. Of course, it necessarily follows, that cohesion does not arise from absolute contact of parts; and that, in fact, absolute mathematical contact, as it is called, cannot possibly exist.

Let us now proceed to unfold the theory. The first elements of matter, according to Boscovich, are, *points* altogether inextended and indivisible, disseminated in an immense vacuum, and placed at certain distances asunder. These distances may be increased or diminished, but cannot altogether vanish, without an absolute compenetration of particles; for their possible contiguity he altogether denies. These particles he conceives

endued with inertia; persevering, if single, in their state of rest, or uniform rectilinear motion.

He conceives two of these *points* of matter to have a determination, at some distances, to approach each other; at others, to recede: and this he calls, the force attractive or repulsive, the magnitude of which changes with the distances, according to some law which may be expressed by an algebraical formula, or, as is common in mechanics, by a curve line. This law of the forces is such, that, in the smallest distances, it is repulsive, increasing indefinitely as the distance is diminished; and is therefore equal to the extinction of any force of approach, however great. At a distance somewhat greater, this force diminishes, so that a very little way off, it vanishes entirely: beyond that, the force becomes attractive, which, as we continue to pass outward, arrives at its maximum, then diminishes and vanishes; after that, a repulsive force takes place again, which, in its turn, increases to a maximum, then diminishes and vanishes; and thus, passing through several alternations, until we arrive, at length, at a force constantly attractive, but diminishing inversely as the square of the distance, which continues at least as far as the limits of our planetary system, and is no other than the general law of Newtonian gravity.

The apparent complication of this, will be best removed, and a general idea of the whole system most readily obtained, by referring to Figure 1. Plate LXV. where the axis CAC' has, in the point A, a perpendicular drawn to it; on either side of which, there are two equal and similar branches of a curve. One of these, DEFGHIKLMNOPQRSTV, has, in the first place, the asymptotic arc ED. That is, if it were produced towards the parts BD, beyond any whatever limits, though it will constantly approach nearer to the line AB, and come at length within less than any assignable distance from it, yet it will never meet it. On the other hand, the curve in the direction DE, constantly recedes from the same right line, (nay, even all the other arcs towards V, successively recede from it), and first approaching the axis CC', meets it somewhere in E, cuts it, and departs off to a certain distance F; from whence it begins again to approach the axis, and cuts it again in G; and thus winds across the axis CC' for several times, until, at length, it ends in another asymptotic branch TpsV, which approaches the axis so that the distances from it are apparently in the duplicate ratios of the corresponding distances from the centre A.

It is hardly necessary to inform the scientific reader, that if from any points of the axis, as *a*, *b*, *d*, there be drawn perpendiculars *ag*, *br*, *dh*; any segment of the axis, as *Aa*, *Ab*, *Ad*, is called an abscissa, and refers to the distance between the two points of matter; while the perpendicular *ag*, or *br*, or *dh*, is called the ordinate, and exhibits the mutual force, repulsive or attractive, according as it lies on the side of the axis towards D, or on the opposite side.

Now, it is plain that in this form of the curve, the ordinate *ag* increases beyond any limits whatever, if the abscissa *Aa* is diminished equally beyond any given limits; that if this abscissa be increased as in *Ab*, the

ordinate is diminished as in br ; and so continually, until it arrives at E , where the ordinate vanishes. Then the abscissa being increased to $A d$, the ordinate changes its direction into dh ; and on the opposite side will increase, first towards I , and then decrease by il as far as G , where it vanishes; and again will change its direction into the former, as at mn , and so, after several changes, the ordinates come to have a constant direction, as in op , qs , sensibly decreasing in the inverse ratio of the squares of the abscissas $A o$, $A v$. Wherefore it is manifest, that, by a curve of this kind, these forces may be expressed; first repulsive, and in the smallest distances increasing indefinitely as the distances are diminished; lessening as these are increased; then vanishing; then, with a change of direction, passing off into attractive forces, which also, in their turn, vanish; and at length, after several changes, they become, in distances sufficiently great, attractive in the inverse duplicate ratio of the distance.

This curve, which Boscovich has exhibited in a variety of his dissertations, differs considerably from that expressing the Newtonian law of gravity. The latter, which is a hyperbola of the third degree, lies entirely on one side of the axis, and has two asymptotic branches; the one of which, forming a part also of Boscovich's curve, expresses the indefinite diminution of the force of gravity, while the distances are increased; the other, the indefinite enlargement of that force, when the bodies are sufficiently near.

According to Boscovich, however, this indefinite enlargement of the force of gravity, is not only contrary to experiment, but even impossible. He occupies a considerable part of the *Dissertatio de Legibus verum in Natura existentium* in showing that there cannot be attractive forces in the least distances, increasing infinitely. For, in the first place, if these forces act in small distances, they must augment the velocity of approach until absolute contact. At which instant this augmentation, where it has arrived at a maximum state, will be at once destroyed.

Secondly, should these forces thus acting in minute distances, increase in any inverse ratio of the distance, the velocity increasing constantly until contact must be infinitely greater there than at any given distance; a supposition which Boscovich considers as absurd, since an infinite velocity implies a finite space passed over in an instant or point of time. For these, and many other reasons unnecessary for us to repeat, Boscovich has rejected the possibility of any attractive force acting in the most minute distances, let the law of action be what it may. But the whole of these difficulties cease at once, were we to suppose that a repulsive force, equal to the extinction of any given velocity, should act in the like situations, since that force must hinder entirely any mutual access or concurrence.

But it will in all probability be better for us to follow our author, in the account he has given of the way in which the essential parts of this theory were originally suggested to him.

In writing a dissertation *De viribus vivis*, or concerning living forces, as they are called by the followers of Leibnitz, and in which he derived all those things commonly referred to the *vires vivæ*, from the sole velocity generated by the powers of gravity, elasticity, &c., he began to enquire more carefully into the velocity produced by impulsion; where, since the velocity is sup-

posed to be acquired in a moment of time, the force is said to be infinitely greater than any pressure. And it occurred to him, that the laws of percussions of that kind must be very different from the other. But, upon more mature reflection, it appeared, that this notion was inadmissible, since nature every where employed the same mode of action; and that immediate impulse or percussio could not exist without the production of a finite velocity in an indivisible moment of time, without a certain *saltus* and breach of what is called the law of continuity, a law which he conceived really to exist in nature, and to be sufficiently demonstrable.

For instance, let two equal bodies be conceived moving in the same direction; A, which precedes, with the velocity 6, and B following with the velocity 12. After collision, it is well known they both proceed with the velocity 9. Now, if each of the bodies retains its velocity until the very moment of collision, it must follow, that at that very instant, the one diminishes its velocity, while the other increases, and each of them abruptly, *per saltum*, viz. A passing from 6 to 9, and B from 12 to 9, without any transit through the intermediate degrees, 7 and 11, 8 and 10, $9\frac{1}{2}$ and $8\frac{1}{2}$, &c. For it would be absurd to say, that during the contact any change through the intermediate degrees can take place; for the anterior parts of B, which is, by hypothesis, moving faster, must, in the small portion of time which elapses between the beginning of the contact and the acquisition of the common velocity, have penetrated the posterior part of A, contrary to the acknowledged properties of matter. The change must, therefore, be abrupt; and, consequently, involve a breach of the law of continuity, according to which it is altogether impossible to pass from one degree of magnitude to another, without also passing through all the intermediate degrees.

There are many who get rid of this difficulty, by denying altogether the existence of bodies perfectly hard, or incapable of compression, and by alleging that the change of velocity takes place during the introcession or compression of the parts of the bodies, without any breach of the law of continuity.

But this argument is of no avail to those who, with Newton and most of the ancient philosophers, suppose the first elements of matter to be altogether hard and solid, incapable of change of figure. For, what are we to make of the meeting of two atoms, or two monads, or by whatever other name we designate these primary particles of matter?

Maclaurin saw this difficulty, when contemplating the collision of bodies, in his *Account of Newton's Discoveries*, book i. ch. 4., and finding that there was no way of preserving the law of continuity inviolate in the case of actual contact, he allowed a breach of it in the collision of hard bodies. He had not the boldness to reject, as Boscovich has done, impulsion and immediate contact altogether, and to insist that a breach of the law of continuity is altogether impossible.

The law of which we are now treating consists in this, that *any variable quantity, whilst it passes from one magnitude to another, passes through all the intermediate magnitudes of the same kind*; by which it is to be understood, not that the different magnitudes are formed by certain small and momentary accessions, for that, as Maupertuis has objected, would be itself a breach of the law of continuity; but that to every particular instant a particular

state corresponds, and that the increments or decrements are only formed during continued portions of time.

That this law of continuity exists in nature, the majority of philosophers do admit. Boscovich conceives that a breach of it is altogether impossible; and has endeavoured to prove so, in several of his writings, by the following inductive reasoning.

The continuity is preserved in every kind of motion, since moving bodies describe continued lines. The planets and comets perform their courses in continued lines; their retrogradations are gradual, and even when they appear stationary, there is always some little motion. The light of day comes in by the morning dawn, and departs by the evening twilight. The diameter of the sun, not suddenly, but by a continued motion, ascends above the horizon, or descends below it. Heavy bodies projected obliquely perform, in like manner, their motions in continued lines, viz. parabolas, if we exclude the resistance of the air; or, if we admit that, in curves approaching the hyperbola. And, indeed, they must always have some little obliquity; it being infinitely improbable that any of them should be so projected, as to ascend and descend in a perpendicular line. Every other motion depending on gravity, as well as on magnetism or electricity, must necessarily follow the law of continuity. Gravity acts universally as the square of the distance; and we evidently see that magnetism and other forces of that kind act much in the same way. In all these, therefore, and the motions dependent on them, the law of continuity is strictly observed, as well in the lines described, as in the velocities acquired. Hence in natural motions there is nothing angular; but the change of direction is always made gradually. And even in bodies themselves there are no exact angles; for, however sharp the point or edge may appear in thorns and prickles, the beaks and talons of birds, or the like, the curvature is always evident, at least through the microscope. The same thing is also to be observed in the courses of rivers, the leaves of trees, the twigs and branches, stones, and the like. In short, if we go through all nature, we find the continuity strictly adhered to, if all things be rightly considered; and it may be enough to challenge a single instance to be produced to the contrary, or where the continued connection is altogether undiscoverable.

From this ample and general inductive reasoning, Boscovich would infer that the law of continuity is really universal; and that, so far from conceding it in those cases where observation seems to contradict it, it becomes us rather to search for some explanation by which they may be reconciled with the general law. To do otherwise, would be to contradict one of the fundamental principles of sound philosophy. For in the investigation of the general laws of nature, there is scarcely any other mode of procedure than by induction. By its means, extension, figurability, mobility, impenetrability, have been always, even by the ancient philosophers, admitted as properties of matter; and, in like manner, later philosophers have to these added inertia and general gravity. And although even in these, there appear to be some bodies which admit of a deviation from these general laws, yet a careful examination enables us to give a rational explanation of such cases, reconcilable with them; and therefore we consider such cases as no ways militating against the acknowledged principle. For example, because we see so many of the bodies that we have among our hands resist others when we

try to make them occupy the same place, and rather giving way when the resistance is unequal, we admit the impenetrability of bodies; nor does it prevent us from doing so, that there are some which may insinuate themselves into other and even very hard bodies, as oil into marble, light into glass and gems; for this phenomenon can be easily reconciled with impenetrability, by saying that these bodies penetrate through the pores and openings of the others.

Now the proofs by induction of the law of continuity, are as abundant and as convincing as those for the impenetrability of matter. We sometimes make abrupt passages in our minds. Thus in physics, if we conceive the length of a day to be the interval from sunset to sunset, or from sunrise to sunset, we say, the preceding day dithers from the following by some seconds, where there appears no intermediate day which differs less: but if we take all the places on the same parallel, we find a series composed of days of all the intermediate lengths, the first of which was the preceding, and the last, the following day above spoken of. In like manner, we say one oscillation of the pendulum is shorter than the preceding, not observing, that if we were to subdivide the arcs, and compare corresponding parts, we would find the change of velocity gradual throughout the whole course of the oscillation. The *saltus*, therefore, is not in nature, but in our minds. We are often apt to confound a quick motion with an instantaneous one; and to suppose something done in a moment, which, in fact, is done in a continued, though very short space of time. Thus some will say, that a stone thrown from the hand, or water spouting from a vessel, acquires instantaneously a finite velocity. But in the former case it is evident, that a finite velocity can by no means be produced in a moment. There must be some time, however little, for the mind to act upon the nerves and muscles, for the extension of the fibres and the like; and if we would give any sensible velocity to the stone, the hand must be drawn back, and the stone held for some time, until by returning it forwards, and perpetually accelerating it, we communicate to it the requisite velocity. In like manner, the ball is not thrown out abruptly from the gun: for a certain space of time will be requisite ere the whole of the powder be inflamed, the air dilated, that by its elasticity the ball may be gradually accelerated.

But however satisfactory this inductive reasoning may be, our author has adduced other arguments to shew, that a breach of the law of continuity is metaphysically impossible. These arguments he derives from the very nature of continuity. As was long ago observed by Aristotle, the limit which joins the precedent conditions with the consequent, must, in that respect, be common to both, and therefore indivisible. Thus the superficies, which is the common boundary of two solids, is destitute of thickness; the line separating the two parts of a continued surface, has no breadth; and a point separating the segments of a continued line, is altogether indivisible. Thus also in time, when an hour ends, the next immediately begins, the common boundary being an indivisible instant. Neither can two instants be chosen so contiguous, but that a finite portion of time must intervene between them, which is again divisible *ad infinitum*. Thus also in any variable quantity, since all variations are made in time, they all partake of its continuity; and to every instant which may be assigned, a certain state of the variable quantity will correspond: As after the sixth hour we cannot have the 9th, without

having previously the 7th and 8th; so in motions, you cannot go from the distance 6 to the distance 9, without previously passing through the distances 7 and 8; for in that instant of passage, you would be both at the distance 6, and at the distance 9, which is evidently impossible. The same thing may be said of density, of heat and cold in the thermometer, and the weight of the air; and, in fine, of all variable quantities.

But against this argument it may seem, that in creation from nothing, or annihilation, the passage is made *per saltum*: Our author replies that it is not; that, in these cases, there is no passage from one state to another; that non-existence is no state, but a mere nothing, which, of course, has no properties or boundary. Of a finite, real and existing series, there must be real and existing limits: But nothing has no limit; and therefore, in creation, a body passes over no intermediate state. It begins to exist, and to have a state, and existence is not divisible. In passing from positive to negative quantities, have we not a *saltus*? In changing from attraction to repulsion, have we not a breach of continuity in our very theory itself? To this we answer, that the attractive forces diminish through all intermediate degrees down to nothing, through which, as a limit, they pass to repulsion. Nothing here, however, does not properly imply non-existence, but is merely relative, and expresses the limit between two different variable states of existence, as the single parabola is the limit between the infinite variety of the ellipse and hyperbola.

In this sense, too, rest is a real state of existence; so is no velocity, or perseverance in the same place, no force or perseverance in retaining the previous velocity; and so of others. These differ greatly from non-existence. When, in the solution of a problem, we arrive at a quantity of the former description, the determination is real, though of a peculiar kind. But we arrive at an expression of the latter kind only, where the problem is impossible.

From what we have now said, we believe that the general law of continuity is sufficiently manifest; and it will be hardly necessary for us, as Boscovich has done, to prove that, upon the same principles, the change from one velocity to another never takes place but by passing through all the intermediate velocities. For example, if there was an abrupt passage from the velocity 6, arising from all the preceding circumstances affecting the moving body, to the velocity 9, then, at the very instant of the passage, we have a determination to two different velocities, which, as already shown, would be absurd.

It is therefore evident, that the whole velocity of a body, can neither be created nor extinguished in a moment; and consequently, in the collision of two bodies, there must be a breach of the law of continuity, if the contact takes place with any determinate difference of their velocities. Let us see what must happen, if no such breach be admitted, since these bodies cannot come into contact with the previous velocities. The velocities must begin immediately to change, either by the increase or diminution of one or both. The cause of such a change as this, is called a force; and there must consequently be some force acting to produce this effect, even though the bodies have not yet come into contact.

To prevent the breach of continuity, it would be sufficient that the forces should act only on one of the bodies; but from the principle of the equality of action and

reaction, for which there is abundant evidence by induction, we must suppose, that this force is mutual between them, increasing the velocity of the one at the same rate as it diminishes that of the other. This is, in fact, producing a sort of opposite velocities, by which, if the bodies were impressed alone, they would be made to recede. The force is therefore repulsive, and it becomes us to enquire into the laws by which it is regulated. In the case above mentioned, where A, moving with the velocity 6, is overtaken and hit by B, moving with the velocity 12, it would be enough, that the repulsive power which we have now discovered, should be able to extinguish the 6 degrees of difference of velocity, and the actual contact might take place at the very moment in which the velocities became equal. But should B, following with 20 degrees of velocity, hit A with 6, the difference or relative velocity is 14; and though the repulsive power be equal to the extinction of 6 degrees, there is still a difference of 8 at the time of contact; nay, there must be even a greater difference than 8 degrees; for the repulsive power will have less time to act than in the former case, and therefore, agreeably to constant experience, it must produce a less effect than before.

The contact of the two bodies would therefore take place, although the difference of their velocities be even greater than 8 degrees, and we should have the same breach of continuity that we have already demonstrated to be impossible. Nature therefore will provide for this, as for the former case; and at a distance more minute, an additional force will take away all the 14 degrees of difference even before the contact takes place. But when we have come thus far, it is evident that there can be no limits assigned to the increase of the repulsive power, which acts between the two bodies hindering their approach. It must be equal to the extinction of any velocity, however great. We must therefore admit, that the repulsive forces, as the distances are diminished, increase *ad infinitum*: that is, we must admit the existence of the asymptotic arc ED of the curve in Fig. 1st, which exhibits the law of impenetrability, and that the actual contact of bodies or particles is altogether impossible.

This perhaps is not the only asymptotic arc in the curve of forces: There may be others, or a succession of them—a circumstance which opens a fertile field of contemplation. But we proceed to those branches of the curve for which we have undoubted evidence.

In the first place, the gravity of all bodies, which is daily experienced, evinces, that the repulsive forces which we discover in the smaller distances, is by no means indefinitely extended; but in the greater distances, gives places to a force of attraction: and the laws of Kepler, in astronomy, so happily reduced by Newton under the single law of general gravity, sufficiently shew, that this attraction, if it does not extend *ad infinitum*, must, at least, pass as far as the utmost limits of the planetary and cometary system. The curve, expressing the law of forces, has therefore another arc STY, which, to all sense, is the same with that hyperbola of the third order, of which the ordinates are reciprocally in the duplicate ratio of the distances or abscissæ. But it is evident that there must be some place E, where this curve cuts the axis, and in which the transition is made from attraction to repulsion.

The phenomena of vapour arising from water, and of air produced from fixed substances, exhibit to us two other limits of the same kind: For in these there is at

first no repulsion, but rather an attraction and coherence. Nevertheless their expansion and elastic force are afterwards sufficient manifestations, that a repulsive force exists among their particles. We have therefore, first, a transition from the primary repulsion to attraction; then to repulsion again; and lastly, to the general attraction of gravity. But indeed there appears to be many such limits and transitions; for without them the numerous effervescences and fermentations in which the particles approach and recede so variously, and the phenomena especially of soft bodies, are not otherwise to be explained.

The whole form of the curve of forces being now elicited, by direct reasoning, from the phenomena, it remains to determine the constitution of the primary elements of matter, as deduced from those forces; and this being done, the theory, as proposed in the beginning of this account of it, may be legitimately applied to mechanical and physical science.

Seeing that the repulsive force, in lessening the distance, increases *in infinitum*, it is evident, that no particle of matter can be contiguous to, or in contact with, another. The first elements of matter must therefore be altogether simple, and composed of no contiguous parts. They must be also inextended.

We need not therefore be perplexed with the questions, whether any division of a real being can be carried *ad infinitum*? or, whether the number of distinct and separable parts of matter be finite or infinite? or any of the numberless difficulties which arise from the supposed continued extension of body, and which philosophers have hitherto been so much puzzled to explain: For if the first elements of matter are points altogether inextended, indivisible, and separated by some interval, the number in any given mass must necessarily be finite. The density of a body may be indefinitely increased as well as diminished; since the distance between the particles may be indefinitely diminished; but upon the supposition of solid and extended elements, there is an evident limit to the increase of density, even when the particles come into contact.

With the simplicity and inextension of the primary particles, we should also admit their homogeneity. The arch of the curve expressing impenetrability, and the exterior arc exhibiting gravity, are always the same; for all bodies are equally impenetrable, and for their quantity of matter are equally heavy. It is therefore exceedingly improbable, that there should be any variety in the other parts of the curve among different particles; or that it should be different in different directions from the same particle. Besides, such a variety is unnecessary, since it can, as we shall soon see, be sufficiently provided for, from the variety in the number and position of the points composing the sensible particles of matter.

The objections to this doctrine, which are urged by the Leibnitzians, derived from the principle of indiscernibles, and of the sufficient reason, (See LEIBNITZ.) Boscovich removes, by expressing his conviction, that the infinite mind of the Divinity can perceive the individuation of objects altogether similar; and, with respect to the sufficient reason, he contends for its falsity, as being founded on the principle of necessity, maintained by Leibnitz; and as to the argument from induction, derived from the wonderful variety we find in nature, where not two leaves in a forest are exactly the same, he says, all this variety may be completely produced by

the various arrangement of the points of matter, seeing their number is so great. This he illustrates, by supposing an immense library of books in various languages, the letters in which were formed by small round points, placed so near each other, that the interval could only be discovered by the help of the microscope. Now should any person, ignorant of languages, and of this kind of writing, begin diligently to examine this collection, he would first find out of the vast multitude of words, a certain number which occurred often in some of the books, and in others never appeared; and collecting these together, he might form dictionaries of the several languages. But upon further investigation, it would be found, that the whole of these words were expressed by the help of only twenty-four different letters; and here he must stop, unless he could procure farther assistance: But suppose him provided with a microscope, he would at length discover, that by the various arrangements of single points, were formed the whole of the letters, words, languages, and books, on various subjects, that composed this great collection. Just so, says Boscovich, is it in chemistry, where the farther we push our analysis, the more nearly do we arrive at elements, simple and homogeneous. And thus we have detailed the whole of the proofs which Boscovich has given for his system: but before going farther, it will not be improper to follow him also in refuting some of the objections which have been, or may be, proposed against its general reception.

Against mutual attractive and repulsive forces, it has been usual to object, that they are no better than the occult qualities of the Peripatetics, and that they induce action at a distance. The same objection has been made to the Newtonian theory of gravity; but the answer is easy, we observe the effects, which are sufficiently manifest. We must admit for them an adequate cause. Whether that be the immediate act of the Creator, or some mediate instrument which he employs, we are unable to determine. With respect to action at a distance, there is, at least, nothing more occult in that, than in the production of motion by immediate impulse. Newton has given a satisfactory explanation of the phenomena of light; and has reduced mechanical astronomy to rigid calculation, without employing impulse; and it is highly probable, that we may be equally successful in other departments of nature.

It has been objected, that the theory itself admits of a breach of continuity, in passing suddenly from repulsion to attraction; but this we have already shown to take place, by passing through all the intermediate degrees, in the same manner as the change is made from positive to negative quantities, by a continual subtraction.

It may be objected, that the complication of the curve, made up of many arches, repulsive and attractive, is no better than the old doctrine of the arbitrary qualities and substantial forms. Boscovich answers, that repulsion is but a negative attraction, as may be illustrated by algebraic equations, and geometric loci: and again, that, supposing us entirely ignorant of the law of mutual forces, it is at first much more likely, that the curve, which expresses it, is of a high than of a low order; that is, it is much more likely that it frequently intersects the axis, or has frequent flexures, than otherwise; seeing that the higher orders of lines are so much more numerous than the lower. But, independent of this conjecture, the form of the curve has been derived by positive argument from the phenomena; and it is

well known, that there are many curves which, from their nature, must form frequent flexures and intersections with the axis. To our minds, the mutual congruity of straight lines, upon which, by the way, the whole of our geometry depends, makes them appear the simplest of any, and others to be the more complicated, only as they remove the more from the right line. But all continued lines of uniform nature are equally simple; and a mind may be conceived, to which the parabola, for instance, might appear as essentially simple, as to us appears the straight line. But besides this general reply to the objection before stated, Boscovich has shewed, in his Dissertation *de Jęge Virium*, that this curve is uniform and regular, and may be expressed by one general algebraic equation.

For this purpose, six conditions are proposed, as requisite to the complete expression of the law of forces. 1st, The curve must be regular and simple, and not composed of an aggregate of different curves. 2d, It must cut the axis CAC' only in certain given points, at equal distances on each side, as AE' AE, AG' AG, AI' AI, and so forth. 3d, To every absciss there must be a corresponding ordinate. 4th, To equal abscisses on either side, equal ordinates must correspond. 5th, The straight line AB must be an asymptote to the curve on either side, and the asymptotic area BAED must be infinite. 6th, The arch, intercepted between any two intersections, may be varied at pleasure, may recede to any distance from the axis, and may approach at pleasure to an arch of any other curve, cutting, touching, or osculating it, in any place, or in any way that may be proposed.

I. That these conditions may be fulfilled, he finds an algebraic formula which contains his law, calling the ordinate as usual y , and the abscissa $=z$, he takes $x = z$. Let all the values of AE, AG, AI, &c. be taken with the negative sign, and let the sum of the squares of these values be called a ; of the products of every two squares be called b ; of every three c , and so on; and let the product of all of them be called f , and let the number of values be called m . Now put

$$= m + az^{m-1} + bz^{m-2} + cz^{m-3} + \dots + f = P.$$

If we suppose $P = 0$, it is clear that all the roots of the equation will be real and positive, namely the squares of the quantities AE, AG, AI, which are the values of z , and since $x^2 = z$, $x = \pm \sqrt{z}$, it is plain that the values of x are as well AE, AG, AI, positive, as AE', AG', AI' negative.

II. Next, let any given quantity be taken for z , only that it may not have a common divisor with P ; and z vanishing, it will also vanish; and x being made an infinitesim of the first order, it will also become an infinitesim of the same, or a lower order, as any formula $zr + gz^{r-1} + hz^{r-2}$, &c. $+ b$, which being put $= 0$, may have any number of imaginary, and any number of, and whatever real roots; (but none of them $= AE, AG, \&c.$ either positive or negative;) if then the whole be multiplied by z , let that be called Q .

III. If now we make $P - Qy = 0$, this equation will fulfil all the conditions proposed but the last; and that may be fulfilled in an infinite number of ways, by properly determining the value of Q .

For, in the first place, since the values of P and Q , put equal to 0, have no common root, they have no common divisor, and therefore the equation can-

not by division be reduced to two; it is therefore simple, and expresses one simple and continued curve, which is not composed of others. This is the first condition.

Next, a curve of this kind will cut the axis CAC' in all the points E, G, I, E', G', &c. and only in these. For it can only cut the axis in those points in which $y = 0$, and it will cut it in all these. Besides, when $y = 0$, $Qy = 0$, and since $P - Qy = 0$, therefore $P = 0$, which can only happen when z is one of the roots of the equation $P = 0$; that is, as we have already shown, only in the points E, G, I, &c. or E', G', &c. Wherefore the quantity y vanishes, and the curve cuts the axis only in these points. That the curve will cut it in these points, is also clear from this, that in each of them $P = 0$, therefore also $Qy = 0$, and it is not $Q = 0$, for there is no common root of the equations $P = 0$ and $Q = 0$; therefore it must be $y = 0$, and consequently the curve meets the axis: which fulfils the second condition.

Besides, since $P - Qy = 0$, $y = \frac{P}{Q}$; and if any abscissa x be given, z is also given, and therefore P and Q are single and determined, and therefore y is also single and determined. To every absciss x , therefore, there is a corresponding ordinate y , and only one. This is the third condition.

Again, whether x be assumed positive or negative, while it is of the same length, the value of $z = x^2$ is always the same; and therefore the values of P, Q , and consequently of y , must be the same. So that if equal abscisses be taken on each side of A, the corresponding ordinates will be equal: which is the fourth condition.

If x be diminished *in infinitum*, whether it be positive or negative, z will also be diminished *in infinitum*, and will be an infinitesimal of the second order. Wherefore in the value of P , all the terms will decrease *in infinitum*, f only excepted, because all the rest besides it are multiplied by z ; and thus the value of P will be as yet finite. But the value of Q , which involves the formula drawn entirely into z , will diminish *in infinitum*, and will become an infinitesimal of the second order. Therefore $\frac{P}{Q} = y$ will increase *in infinitum*, and becomes an infinitely great quantity of the second order. Wherefore the curve will have for its asymptote the straight line AB; and the area BAED will increase *in infinitum*, and if the positive ordinates y are taken towards the parts AB, and express the repulsive forces, the asymptotic arc ED will be towards the same parts AB: which was the fifth condition.

It is clear, then, that however Q be assumed with the given conditions, the first five requisites will be fulfilled. Now the value of Q may be varied in an infinite number of ways, so as still to fulfil the conditions with which it was assumed. And therefore the arc of the curve intercepted between the intersections may be varied in infinite ways, so that the first five conditions may be fulfilled. It may therefore be varied so as to fulfil the sixth condition. For if there be given however many, and whatever arches of whatever curves, providing they be such that they recede always from the asymptote AB, and thus no right line parallel to that asymptote cut these arches in more than one point, and in them let there be taken as many points as you please, and as near one another; it will be easy to assume such a value of P , that the curve may pass through all these points, and

the same may be varied infinitely; so that still the curve will pass through all the same points. Let the number of points assumed be what you please $\equiv z$; and from every one of such points, let right lines be drawn parallel to AB, as far as the axis CAC', which must be ordinates of the curve that is sought; and let the abscissas from A to the said ordinates be called M^1, M^2, M^3 , &c. and the ordinates N^1, N^2, N^3 , &c. Let there now be taken a certain quantity $Az^r + Bz^{r-1} + Cz^{r-2} + Gz$, and let this quantity be supposed equal to R. Then let another such quantity T be assumed, so that z vanishing, any term of it may vanish, and so that there be no common divisor of the value of P, and of the value of $R+T$, which may be easily done, seeing all the divisors of the quantity P are known. Let it now be made $Q \equiv R+T$, and then the equation of the curve will be $P - Ry - Ty \equiv 0$. After this, let there be put in the equation M^1, M^2, M^3 , successively for x , and N^1, N^2, N^3 , &c. for y ; we shall have r equations, each containing values of A, B . C . . . G, of one dimension, besides the given values of M^1, M^2, M^3 , &c. N^1, N^2, N^3 , &c. and the arbitrary values, which in T are the coefficients of z .

By these equations, which are in number r , it will be easy to determine the values of A, B, C, . . . G, which are likewise in number r , assuming in the first equation, according to the usual method, the value A, and substituting it in all the following equations, by which means the equations will become $r-1$. These, again, by throwing out the value B, will be reduced to $r-2$, and so on, until we come to one only, in which the value Q being determined, by means of that, in a retrograde order, all the preceding values will be determined, one by each equation. The values A, B, C, . . . G being in this manner determined in the equation $P - Ry - Ty \equiv 0$, or $P - Qy \equiv 0$, it is clear that the values M^1, M^2, M^3 , &c. being successively put for x , the values of the ordinate y must successively be N^1, N^2, N^3 , &c.; and therefore that the curve must pass through these given points in those given curves, and still the value Q will have all the preceding conditions. For z being lessened beyond whatever limits; seeing all the terms of the value of T are lessened which were thus assumed, and likewise the terms of the value R are lessened, which are all multiplied by z , and besides this there will be no common divisor of the quantities P and Q, seeing there is none of the quantity P and $R+P$.

But if two of the nearest of the points assumed in the arches of the curves, on the same side of the axis, be supposed to accede to one another, beyond whatever limits, and at last to coincide, which will be done by making two M equal, and likewise two N equal, then the curve sought will touch the arch of the given curve there, and if three such points coincide, it will *osculate* it; nay, as many points as we please may be made to meet together where we please, and thus we may have *osculations* of what order we please, and as near one another as we please, the arch of the given curve approaching as we please, and at whatever distances we please, to whatever arches of whatever curves, and yet still preserving all the six conditions required for expressing that law of the repulsive and attractive forces. And whereas the value of T can be varied in infinite manners, the same may be done in an infinite number of ways, and therefore a simple curve, answering the given conditions, may be found out in an infinite number of ways. Q. E. F.

It would be very possible to divide this curve, though single in itself, into two or more. Thus, if any one should wish to consider general gravity as accurately reciprocally as the squares of the distances, he may describe on the attractive side the hyperbola which expresses it, which, in fact will be a continuation of the leg VTS, then to each of the ordinates ag, hd , of the curve of forces, Plate LXV, Fig. 1. he may add the ordinates of this new hyperbola towards the parts AB, beginning at the points g and h of the curve. By which means a new curve will arise, coinciding to sense with the axis, towards the parts V γ , but elsewhere at a distance from it, and even winding about it, if the vertices F, K, O, are more distant than the hyperbola is. In this way even many different forces may be expressed, which, as in the resolution of forces, may sometimes be found useful in more readily demonstrating the effects. And, in fact, it will be a true resolution of forces: but, nevertheless, it is merely the offspring of the mind.

As we have mentioned the decrease of gravity to be accurately in the reciprocal duplicate ratio of the distance, which is generally admitted by the cultivators of mechanical astronomy, it may seem an objection against our theory, that it departs so widely from that law. But, in the first place, the action of the particles in the lesser distances does very much differ from that law, seeing that vapours, which exert such a great force of expansion, must have, in these distances, a repulsion to each other, and not an attraction, and that even the attraction of cohesion is vastly greater than that which should be produced by general gravity; and hence some of the disciples of Newton have supposed a force corresponding to this formula $\frac{1}{x^3} + \frac{1}{x^2}$, the former part of

which is immensely less than the latter when x is much greater than the assumed unity, but is greater than it when x is much less; so that in the greater distances the force is very nearly inversely as the squares, and in the less very nearly as the cubes of the distances. So that the duplicate ratio is not strictly adhered to even among the Newtonians.

It has indeed been demonstrated by Newton, that the line of apsides of the planets would have an immense motion, if the ratio of forces were very distant from being inversely as the squares of the distances. But they have some motion, and it is not enough to say that this is owing to the disturbing force of the other planets, for this is not yet accurately demonstrated; and indeed it is only after many attempts and approximations, that a partial solution has been given of the celebrated problem of three bodies, in which there is sought the motion of three bodies acting on each other in the inverse duplicate ratio of the distances. It may be guessed, therefore, how far we yet are from having any demonstration of the strict accuracy of this law of forces.

To many the greatest difficulty in the theory appears to be the total rejection of immediate contact, which, they think, is evidently shown by the testimony of the senses; a rod, they say, should be used to him who denies contact. But it is admitted, that bodies approach so near each other as to leave no sensible distance between them; and that the resistance we experience is produced by the repulsive power, which gives us the same sensation as actual contact is supposed to do: the contact being *physical*, although not *mathematical*.

So much for the objections which may be made to the

proposed law of the forces. Let us next enquire into those made to the constitution of the primary elements, deduced from that law.

In the first place, there are many who can by no means be persuaded to admit the existence of points altogether indivisible and inextended, alleging that they cannot possibly form any idea of them. Because all the bodies cognisable by the senses are extended, we are apt to look upon extension as essential to matter. But this error may be corrected by reflection; and the idea of an inextended point may be formed by the help of geometry, and that very idea of continued extension, which is so familiar to our senses. Thus the common section of two contiguous parts of a plane surface is a mathematical line, destitute of breadth, and the meeting of two such sections is an indivisible point.

We may here observe that Zeno among the ancients, and Leibnitz among the moderns, held that the first elements of matter were simple and inextended; but they were guilty of an inconsistency in maintaining that these were contiguous to each other, and thereby comparing a continued extension of indivisible and inextended elements.

There are some who say that if the elements of matter are void of extension, they are in no respect different from spirits. But the chief difference between body and spirit is, that the one is tangible and incapable of thought or volition, the other may think and will, but does not affect the senses. For sensibility does not consist in extension, but in impenetrability, by which the fibres of the body are affected, and the rays of light are reflected.

But if substances capable of cogitation and volition were endued with the same law of forces, would they not produce to our senses the same effects as these points? We answer, that it is not our business to enquire whether such a conjunction could take place or not.

Such a body would neither be matter nor spirit, but a thing differing from both; from the one by its power of cogitation, as from the other by its inertia and impenetrability.

Application of the Theory to Mechanics.

The second department of our subject is, the application which may be made of this theory to the explanation of the principal laws of equilibrium, and other parts of elementary mechanics. But, in the first place, a few observations are to be premised respecting the curve of forces, upon which all the phenomena depend. These observations relate to the arches of the curve, to the areas intercepted between it and the axis, and to the points in which the curve cuts the axis.

The arches are either repulsive or attractive, according as they lie on the side of the asymptotic arc EG, or on the opposite side. The arches may touch the axis, or they may bend from it with a contrary flexure, as P e f g R, Plate LXV. Fig. 1.

The area corresponding to any small portion of the axis may be ever so great, and that which corresponds to a great segment may be ever so small, according as the curve recedes very far from the axis, or approaches very near to it. It were easy to demonstrate this, but we shall not occupy the reader's time with it. The area included between an asymptote and any ordinate, may

be either finite or infinite. The former, when the ordinate increases in a less ratio than the reciprocal simple ratio of the abscisses; the latter, when it increases in that or in a greater ratio, as may be thus proved. Take x the ordinate as A a , Fig. 1, and y the absciss $a g$, and let $y^n = \frac{1}{x^m}$ or $y = x^{-\frac{m}{n}}$; then the fluxion of the area xy

will be $= x^{-\frac{m}{n}} x$ and its fluent $\frac{n}{n-m} x^{\frac{n-m}{n}} + A$, or since $x^{-\frac{m}{n}} = y$, we have $\frac{n}{n-m} xy + A$; A being a constant

quantity. Since the area begins in A, the beginning of the abscisses, if $n-m$ be a positive number, and therefore $n > m$, the area will be finite, and $A = 0$: But the area will be to the rectangle A ag as n to $n-m$; which rectangle, since ag may be great or small without limit, is also without limit. Its value is infinite, if $m=n$, for then the divisor $= 0$; much more then if $m > n$, that is, when the ordinate increases in a greater than the reciprocal simple ratio of the abscisses. This observation was necessary, that we might have some scale of velocities in the access or recess of one point from another. For, as already observed, when the spaces are expressed by the abscisses, and the forces by the ordinates, the area described by the ordinate expresses the increment or decrement of the square of the velocity.

With respect to the points in which the curve meets the axis, they are either points of section, as E, G, I, or of contact. In the former, there is a transition from attraction to repulsion, or the contrary, and these by our author are called limits. These limits are of two kinds; first, where the transition, by an increase of distance, is from repulsion to attraction, as is the case at E, I, N, R, which are called *limits of cohesion*, for in such a situation the points resist all change of position, viz. separation by means of the attractive force which immediately begins to operate, and mutual approach in like manner by the incipient repulsion. But in the limits of the second kind, as G, L, P, where the transition, by an increase of distance, is from attraction to repulsion, although the points in such situations do not exert any force on each other, yet the smallest change of distance produces a very important alteration: for if they be in the least separated, the repulsive force then acting will remove them still farther asunder; and, on the other hand, if their distance be diminished in the least, they will tend together more and more. Such limits, therefore, are by Boscovich called *limits of non-cohesion*.

The limits of cohesion may be powerful or weak, according to the angle at which the curve intersects the axis, or the distance to which it removes from it. $t N y$ exhibits a limit of the former; $c N x$ of the latter kind. The most powerful kind of limit at first, at least, is, where the curve at cutting the axis has the ordinate for its tangent, as X, Plate LXV. Fig. 6.; and, in like manner, the weakest is, when the axis is the tangent, as Y Fig. 6, both being points of contrary flexure.

This being premised, we now proceed to the consideration of some of the combinations of the points of matter, and of their mutual actions on each other.

If two points be placed at such a distance from each other, as is equal to that of some limit from the beginning of the line of abscisses, as Plate LXV. Fig. 1. AG, AE, &c. and without any kind of motion, they must evidently remain there at rest, since they have no mutual action. But if the points be placed out of limits of that

kind, they will immediately begin to approach or recede by equal intervals. The force continuing in one direction, will carry them to the distance of the nearest limit, which will, of course, be a limit of cohesion. They will arrive at that with an accelerated motion, and the squares of their velocities will be proportional to the area described by the accompanying ordinate. But they will not stop at this limit. Having arrived there with a motion continually accelerated, they will go on beyond it, and, of course, they will be immediately acted on by a force directly opposite. Their motion will therefore be retarded until the velocity be totally extinguished, by the area under this second branch of the curve becoming equal to that intercepted between the ordinate at the original place of the point and the limit aforesaid. Should the area of this second segment be too small, the original motion of the points will go on; they will pass the second limit of non-cohesion, if they arrive at it with the smallest velocity. Beyond that the original motion will be again accelerated by an action of the same kind as at first, and the points will pass another limit of cohesion. A second retarding force will now act, and may at length be equal to the extinction of the velocity. If that does not take place exactly at a limit of non-cohesion, which is scarcely possible, the bodies will be returned again with a series of motions just the contrary of the former, and they will arrive at the same position from which they departed, and they will continue therefore to oscillate in this way for an indefinite length of time.

Cor. The velocity will be greatest at the limits of cohesion, and least at the limits of non-cohesion. No velocity of approach can overcome the repulsion expressed by the first or asymptotic arc, ED. But if the points be placed at first within that arc, the repulsive force may, perhaps, be so great as to carry them over all the subsequent arches, and even through that which expresses the law of general gravity; the points would therefore recede *ad infinitum*.

All this would be the case, were these points left entirely to themselves. But if other external forces act on them, the case might be very different; for these forces may possibly retain the points in limits of cohesion or non-cohesion, or even in situations out of these limits. Should the two points be projected obliquely, with equal and opposite motions, they would revolve in equal curves round the middle point of the line joining them, which curves, if the law of forces were given, might be formed by the inverse problem of central forces. And it may be observed, that if two points be brought towards each other from ever so great a distance, not directly, but with some small obliquity, (and, indeed, direct motion must be hardly possible.) they will not return back, but, from the nature of central forces, will revolve round the middle point of space, always near each other. Although the interval be not cognisable by the senses, this remark will be hereafter of use, when we come to treat of cohesion and of soft bodies.

In treating of the system of three points, the subject, if generally stated, is reducible to the two following problems; viz. 1. Given the position and distances of these points, to find the forces acting on any one composed of the forces by which it is urged by the others, the common law of these forces being given by the first figure; and, 2. Given the law, to find the motions of these points, each of them being projected with given velocities and directions from given places.

The first problem may be solved with comparative facility, either geometrically or analytically, by means of the curve of forces. The second, if it be requisite to define the curves described in every case, either by construction or calculation, exceeds, although the number of points be only three, the powers of the methods yet known; and is, in fact, no other than that celebrated problem of three bodies, so much sought after by the most celebrated mathematicians of our time, and to which, only in some particular cases, and with the greatest limitations, they have been able to give any solution.

It may be remarked, that if the three points be A, B, and C, Plate LXV. Fig. 2., and if the distance of any two of them AB, be bisected in D, DC joined, and one-third of it be taken as DE, however the points be moved by any projection and their mutual forces, the point E will either be at rest, or move uniformly in a straight line. This depends on the properties of the centre of gravity. Therefore, if the points be left to themselves, C will approach to E, and D will likewise, with half of the velocity of C; or else they will recede, or move sideways; but still preserving their relative position and distances with respect to E.

As to their mutual forces. Let there be assumed in Fig. 1., abscisses in the axis, equal to the straight lines AC, BC, Fig. 2.; and taking out the corresponding ordinates, set off CL if the ordinate to AC be attractive, CN if it be repulsive; and, in like manner, set off for BC, CK, or CM. Then, completing the proper parallelogram, its diagonal CF or CH, CI or CG, will exhibit the direction and magnitude of the resulting force, according as the composing forces are both attractive or both repulsive; or one attractive and the other repulsive.

Now, if the point C be supposed to be found always in some indefinite line DE, the resulting force may be found for any number of points in that line; and these ordinates being set off at right angles to the line DE, a curve drawn through their vertices would express the force of the points A and B, at any point in the direction DEC.

Every new direction would require its particular curve; and the force acting on C, at any point in the same plane, could only be expressed geometrically by the perpendicular distance from that plane to a curve superficies.

But it would be more satisfactory to express, not only the magnitude, but the direction of the resulting force. For which purpose, draw FO at right angles to CD, meeting it in O. One curve may express the amount CO of the force, in the direction DEC. for every given distance; and another the value of the perpendicular FO; taking the ordinate on either side of its line of abscisses, according as the action was towards B or towards A.

The force resulting from the action of any number of points disposed in the same superficies, may, in like manner, be expressed by the perpendicular distance at any situation, from a plane to a curve superficies. If there be any of the points, in such a system, situated out of the plane, the force cannot be expressed geometrically in this way, since solidity is the limit of geometric composition. But we are surprised to find a mathematician of Boscovich's eminence say, that geometry is altogether incapable of expressing the law in that case; although it may be done by an algebraic equation with four indeterminate quantities. The *locus ad superficiem*

is indeed insufficient. Neither is it necessary to express an equation of three indeterminates. A geometrical construction is possible for the expression of any algebraic formula. Each of them implies a process to be performed. And the geometric locus differs as completely from an algebraic equation of two or three variable quantities, as a table of logarithms from a formula for finding them. In this case, the geometric construction for any number of points is obvious. It is merely a continuation of that composition of forces, by which the action of two was discovered. It can, indeed, only become definite by supposing all the points given in position; we may then find the amount of the force for that position. But the algebraic equation can do no more, since it can only be applied to use by finding an arithmetical value of any of its roots.

All this while, we have supposed the points A and B to be relatively at rest; but it must be evident that the variety is immense, if we take different positions and distances of these points. Boscovich has enumerated many of the more remarkable cases. It will be sufficient for us to notice a few of the more simple, and those especially which may be referred to in the physical application of the theory.

In the first place, the attraction of C towards A and B, (Plate LXV. Fig. 2) in those greater distances at which the curve of forces sensibly coincides with that of gravity, will always be towards D, proportional to the reciprocal of the square of DC, and sensibly double of what corresponds to that distance in Fig. 1. And the case will be the same in masses consisting of any number of points; the attraction being sensibly the sum of the forces of all the points which constitute these masses.

But in those smaller distances, at which the curve winds about the axis, the actions of the points upon each other will sometimes be attractive, sometimes repulsive, and the forces resulting therefrom will be infinitely diversified. So that, although the force of gravity be universal, and depend only on the mass and the distance, yet those properties, which depend on the action of matter at smaller distances, as the reflection and refraction of light, and the separation of colours; the impressions on the various fibres, in tasting, hearing, smelling, and feeling; cohesions, secretions, nutriments, fermentations, precipitations, explosions, and all the phenomena of chemistry; and a thousand others, however various in their effects, may all be satisfactorily explained on the principles of this theory.

Suppose the point C be placed any where in a line DC, perpendicular to AB; or any where in the line joining them, in Fig. 3. It is evident that, in the first case, the action of B and A being equal and of the same kind, the access or recess of the point C will be in the line DC; and the curve expressing the forces acting on C, might be found by drawing B d equal to any abscisses from Fig. 1; laying off in it, d e its corresponding ordinate; drawing e a at right angles to DC, and making the perpendicular d h equal 2 d a, on any of the sides for repulsion, and on the opposite side for attraction. The curve will cut the axis in various points; it will also pass through the point D, and have a similar branch on the opposite side of AB; in which, however, the sides expressing attraction and repulsion will be reversed. Each intersection will be a limit, and the point D will be a limit of cohesion or non-cohesion, according as the arch on either side of it is attractive or repulsive. It will also be a weak limit, for the op-

posite forces of A and B will nearly destroy each other, although the points be a small matter out of the straight line.

In the second case, where the point C is taken any where in the line AB, the curve which expresses the law of forces may be thus found, in Fig. 4. For any point d, assume two abscisses in Fig. 1, the one equal to A d, the other to d B; and taking the corresponding ordinates, lay off d h equal to their sum or their difference, according as they are of the same or of different kinds, assuming one side of the axis AB to express excess in repulsion, and the other excess in attraction. The curve will pass through the point D, and the directions will be changed as in the former case. If a perpendicular be drawn through B, it will be an asymptote to the curve on either side, since the repulsion of B will prevent absolute contact. There may be several limits or intersections, either between A and B, or beyond them; and according to the distance at which we suppose A and B to be posited, the attractive force of the one may neutralise the repulsive force of the other, or double its attractive force, and *vice versa*.

Let the three points A, D, B, (Plate LXV. Fig. 5.) be in a straight line, their mutual action will be 0, if the three distances AD, DB, AB, be each the distances of limits. The point D may be attracted by both extremes, repelled by both, or attracted by one and repelled by the other. These cases are, however, vastly different; in the first if D be removed from its place to C, it will return to it again; in the second it will recede still farther. In the former case we have an instance of cohesion; in the second of non-cohesion. In the third case, it is plain that the point D will move away from the repelling end, and approach the attractive.

In the first case, the three points may retain, to sense, their rectilinear situation, however powerful the force may be which tends to disturb them. If the force be in the direction of the line, it will be sufficient if, for the middle point, the attraction increases very much with the increase of distance from either extreme; and for either extreme point, if the repulsion decreases very much with the increase of distance from the middle. Should the force be impressed perpendicularly, as, for example, if the middle point be urged in the direction DC, then the forces may be so powerful as at a very small distance to resist any other of the same kind. Should the force constantly urge the point D towards C, and AB to the opposite side, we have a bending or inflexion; and, in like manner, forces acting in the direction of the line joining the points ADB, will produce a compression or dilatation. The forces resisting this may be so powerful as to render this change almost imperceptible, or they may be weak, so as to admit of considerable deviation from the original situation. In this manner we may have an idea of rigidity, and of flexibility and elasticity.

If the two forces AQ, BT, be perpendicular to AB, or parallel to one another, the third force CF will also be parallel to them and equal to their sum, but in the contrary direction. For, draw CD parallel to them, and also KI to AB; and since CK=VB, the triangle CIK is equal and similar to BTV or TBS; and, therefore CI=BT, and IK=BS=AR=QP. Wherefore, if IF be taken=AQ, and KF drawn, the triangle FIK=AQP; and, therefore, FK is equal and parallel to AP or LC, and CLFK is a parallelogram, the diameter of which, CF, express-

es the force of the point C, is parallel to AQ and BT, and is equal to their sum, but in the contrary direction. Also, since $SB : BT$, as $BD : DC$, and $QA : AR :: DC : DA$; therefore, by equality, $AQ : BT :: BD : DA$; that is the forces in A and B are in the reciprocal ratio of the distances AD, DB, from the right line CD, drawn through C in the direction of the forces.

This theorem is general, and applies equally to the mutual action of three points having any position, whether in a right line or not. But its application to unequal masses makes it much more general, and will lead us to the equilibrium of the lever, centres of oscillation, percussion, &c.

If the three points do not lie in a straight line, they will be in equilibrio only when the distances expressing the sides of the triangle correspond to limits. Let AE, EB, BA, (Plate LXV. fig. 7.) be distances constituting an assemblage of this kind; and let $AE = EB$: let FEOH be an ellipse passing through E, with A and B its foci. Let AN, Fig. 1., be equal to the semitransverse $DO = BE = AE$, and let DB be less than the breadth of the next arcs LN, NP, Fig. 7.; and the arcs NM, NO, Fig. 7., equal and similar. It is plain, that if the point E were moved to C, the attraction of A in CL, and repulsion of B in CM, would compose a force in CI along the tangent, which would return C to E; since BC would be as much shorter than at first as A was longer; and to these equal removals from the intersection, equal ordinates or forces will correspond.

But should the point E, (Fig. 7.) be brought to O, the forces of A and B will be equal and opposite, and no motion will arise, unless the point be otherwise somewhat removed from it, in which case it will recede still farther, and pass with an accelerated motion towards E or H. The points E and H, therefore, are exactly similar to the limits of cohesion in the original curve, Fig 1.; the points F and O are limits of non-cohesion. On the other hand, if the distance BC was that of a limit of non-cohesion, the less distance CB would produce an attraction CK; the greater AC a repulsion; and the resulting force CG would make the point C pass to O. So that, in that case, F and O would be limits of cohesion, E and H of non-cohesion.

The point C, if removed a little from the periphery of the ellipse, will return towards it; for the increasing attractions when it passes without the ellipse, and the increasing repulsion when within it, will compose a force, in either case, tending towards the periphery and the limits of cohesion. This assemblage of three points may even serve to give us some idea of solidity, for if any thing should stop the motion of the point B, Fig. 7., while the point A is made to revolve round it, as from A to A'; the point E will, in like manner, pass from E to E', still preserving the original form of the triangle.—But enough of the system of three points.

The system of four or more points would afford us a much greater variety, were we carefully to examine them. We shall only observe, that if two points be situated in the foci of an ellipse, and two others at the vertices of the conjugate axis, they will form a kind of square or rhombus; and if on the four angles of this square, there be conceived a series of points of the same kind to any height, some idea may be got of the solid rod, in which, if the base be inclined, the whole superstructure will immediately be moved to one side. And the celerity of conversion will depend partly on the magnitude of the connecting forces: for should

that be weak, the upper part of the structure will move more slowly, and the rod will be bent like a switch. And four points may be placed out of the same plane, so that they will powerfully preserve their position, even by the help of a single limit of distance sufficiently powerful: for the four points may be arranged as a triangular pyramid, which will therefore constitute a kind of particle most tenacious of its shape. Of four of these particles, disposed in another pyramid, a particle of a second order may be formed, less firm on account of the greater distance of the primary particles composing it, whence the action of external points upon it will be more unequal. In like manner, of these particles others may be formed of a higher order, still less firm; and thus at length we may arrive at those, which being much greater, are more moveable and variable, upon which chemical operations depend, and of which the grosser bodies are composed; so that we would arrive at the same thing as Newton has proposed in his last optical query respecting his primary and elementary particles, which compose other particles of various orders.

And here we would beg leave to object to Boscovich, that since he has admitted that all the particles of matter may be formed upon the supposition only of one limit of distance, what good reason can be given for supposing, as he has done, that there are a succession of changes from attraction to repulsion, and *vice versa*, according to the change in the distance of his primary points. Surely this is to contradict one of the first rules of philosophising, and to multiply causes without necessity. Would it not have been infinitely preferable, to have proceeded at once upon that supposition, for the existence of which he appears to have brought forward such abundant proof? In so doing, his theory would have appeared abundantly more simple, and equally satisfactory. We can see no use whatever for that vague and Proteus-like law of forces which he has just been establishing, unless it be to use a favourite phrase of his own, to exhibit the *infinita fecunditas theoriarum*. How different from, we had almost said how unsatisfactory in comparison to, the beautiful law of Newtonian gravity, by which the infinite variety of physical astronomy, the more generally it is applied, is the more completely explained! Compared to this, indeed, the theory of Boscovich is like the orbis, the deferents, and the epicycles of our forefathers, which, instead of explaining only tended to multiply the difficulties of our progress in science. But we defer this, and some other remarks, until we have completed our account of the theory, and in the mean time return to its application to mechanics, perhaps the most valuable part of his work, and which is, in reality, little dependent upon this peculiar law of forces.

In proceeding to the consideration of masses, the first subject which offers is, the numerous and important properties of the centre of gravity. These are readily derived and demonstrated from our theory; but are of such importance, that we shall make them the subject of a separate article. (See *Centre of Gravity*.) In the mean time we shall only observe, that our author has demonstrated generally, that in every mass there must be some, and only one centre; he shows by what means it may be generally determined; he points out and supplies the defect of proof in the common way of finding the centre of several bodies; illustrating the subject by the multiplication of num-

bers, and the composition of forces; and he demonstrates the celebrated theorem of Newton, that the centre of gravity is undisturbed by mutual internal forces; consequently, that the quantity of motion in the universe is preserved always the same, when computed in the same direction, and therefore that action and reaction are always equal and contrary.

From this law of the equality of action and reaction, readily flow the laws of collision, discovered at the same time by Wren, Huygens, and Wallis, as is mentioned by Newton, when treating of this very law. (*Prin.* lib. i. Cor. 4. Ax.) Boscovich derives them in this way. Suppose a soft globe or ball goes forward with a less velocity, and followed by another soft globe with a greater velocity, so that their centres be always carried in the line which joins them, and that the one at length hits the other, which is called a direct collision; this hitting, according to our author, is not done by an immediate contact, but before they come in contact, the alter parts of the first and the fore parts of the last are compressed by the mutual repulsive force; and this compression goes on increasing until they come to have equal velocities, then all further access ceases, and, consequently, all further compression; and since the bodies are soft, they exert no mutual force after compression, but continue to go on with equal velocity. And since the quantity of motion will be the same in the same direction, we must, in order to find the common velocity after collision, multiply each mass into its velocity, and divide the sum of these products by the sum of the masses. If one of the globes were at rest, its velocity might be made $\equiv 0$, and, if moving in the opposite direction, it might be taken with a negative value.

From soft bodies, the transition is easy to those which are elastic. In these, after the greatest compression and change of figure, the two globes continue to act on each other, until they recover their first shape, and this action doubles the effect of the former. If the elasticity be imperfect, and the force in losing shape be to the force in recovering it in any given ratio, the effect of the former to that of the latter will also be in a given ratio, (See COLLISION); the deductions of Boscovich being no way different from those given in other elementary treatises.

Proceeding now to oblique concurrence, let the two globes A and C in Plate LXV. Fig. 8. come in a given time, by the right lines AB, CD, which measure their velocities into physical contact at B and D. By the common mode, the effect of the contact is thus explained: Join the centres by the straight line BD, to which, produced if necessary, draw the perpendiculars AF, CH; and completing the rectangles, AFBE, CHDG, each of the motions AB, CD is resolved into two, the one into AF, AE, or BE, BF, the other into CH, CG, or GD, DH. The first of these on each side remains entire; the second, FB and HD, make a direct collision. We must therefore find, by the law of direct collision, the velocities DK, DL, which, according to that law, will be different for different sorts of bodies; and we must compound these with the forces or velocities expressed by the straight lines BL, DQ lying in the same straight lines with BE and GD, and equal to them; therefore BM and DP will express the velocities and direction of the motions after collision. The resolution of motions in this way is considered as a real and actual resolution, the one of which continues unaltered, the other undergoes a change; and in the case which this figure ex-

presses, is altogether extinguished, and then another is produced again. But the thing takes place, in fact, without any real resolution, in the following manner: The mutual force which acts upon the balls B, D, gives to them, during the whole time of the collision, the contrary velocities BN, DS, equal, in this case, to those two, of which the one is commonly supposed destroyed and the other reproduced; these forces, compounded with BO and DR, equal, and in the same direction with AB, CD, and therefore expressing the entire effect of the preceding velocities, exhibit the very same resulting velocities BM, DP. For it is evident, that LO will be equal to AE or BF, and therefore $MO \equiv BN$, and BMNO a parallelogram. In like manner, DRPS is a parallelogram. Wherefore there is no real resolution in this case, but merely a composition of motions; namely, the former velocity persevering by the *vis inertiae*, and that compounded with the new velocity which the forces produce that act in the collision.

In the same manner, when a ball strikes obliquely on a plane, when a heavy body descends on an inclined plane, or is constrained to move in the arch of a circle, by being suspended by a thread, the case may be always explained without having recourse to the resolution of forces or motions, and all the phenomena shown to depend only on the composition of forces: thus the procedure of nature is always simple and uniform. And, indeed, that this is general, appears evident from the theory; since no motion can be partially obstructed, when there is no such thing as absolute contact; and that any point is freely moved in empty space, and at liberty to obey, at the same time, the velocity it had previously acquired, and the forces which arise from all the other points of matter. Accordingly Boscovich can see no necessity for introducing the principle of the *vires vivæ*, which Leibnitz and others have brought forward to explain the common doctrine of the resolution of forces, since those very instances employed to demonstrate their existence may be equally well explained without them. One instance may be given in the oblique collision of elastic bodies. Let (Plate LXV. Fig. 9.) the triangles ADB, BHG, GML, be right angled at D, H, M, so that the sides BD, GH, LM, are each equal to half the base AB; and let BG, GL, LQ be parallel to AD, BH, GM. the ball A, with the velocity $AB \equiv 2$, hits at B the equal ball C, lying in DB produced from the oblique impact, it communicates to it the velocity $CE \equiv 1 \equiv DB$, which it loses itself, and then goes on in BG with the velocity $\equiv \sqrt{3} \equiv AD$. In like manner, if it meets the ball I, it communicates to it the velocity $IK \equiv 1$, while it loses IH; and its velocity in GL is $\equiv \sqrt{2}$; then communicating to L the velocity $OP \equiv 1$, it goes on with the velocity $LQ \equiv 1$, and which it communicates, by direct concurrence, to the ball R. Wherefore, say they, with that force which it had with the velocity 2, it has communicated to four balls equal to it, forces which being each $\equiv 1$, make a total of 4; and since the original velocity was 2, the forces are not as the simple velocities into the masses, but as the squares of the velocities. But in the theory of Boscovich this argument has no force. The ball A does not communicate a part of its velocity AB resolved into DB, TB, to the ball C, and with it a part of its force. There acts upon the balls a new and mutual force in opposite directions, which impresses upon the one the velocity CE, and BD on the other. The velocity of the former ball, expressed by BF, equal and in the same direction with AB, is compounded with the

new acquired velocity BD, and there arises the velocity BG, less than BF from the obliquity of the composition. In like manner, a new mutual force acts on the balls at G and I, L and O, Q and R, and the new velocities of the first ball GL, LQ, zero, compose the velocities GH and GN, LM and LS, LQ and QL, without either any actual resolution or translation of *viva viva*.

In the collision of bodies and reflected motion, it may be observed, that since, by this theory, there are no continuous globes, no continuous planes; the most part of the phenomena above mentioned take place only perceptibly, and not with a strict accuracy. The change of direction in impact is not made in one point, but by a continued curve, since the forces act at a distance, something in the way of AB and DM, Plate LXV. Fig. 10. if the forces act only by repulsion. If there be alternate attractions and repulsions, the body will proceed by a winding course. But it is still evident, that if the forces be equal, at equal distances, the two halves ABQ and QDM are equal and similar. If the plane CO be rough, as must be the case in nature, and as we have exhibited in the Figure, this equality of forces will not take place; but if the inequalities be very small in respect of the distance, the irregularity, from this cause, will also be small; and it must be observed, that all the points within the segment RTS will be in action, which will render the inequality so much the more imperceptible.

In this manner one may observe, that light will be reflected at equal angles, from glass sufficiently polished, although the polishing matter has left some small inequalities. But from surfaces, which are sensibly rough, it must be dispersed irregularly and in all directions.

To apply the theory to the refraction of light, let there be two parallel surfaces AB, CD, Plate LXV. Fig. 11, and a moveable point without them. At some distance it is not acted on by any force, but, within that, is urged by forces which, however, are always perpendicular to the plane. Let it approach either of them in the direction GE, with the velocity HE. Let this be expressed, or, as it is usually called, resolved into the two HS, and SE. After ingress, between the planes, its motion will be incurvated by these forces, in such a manner, however, as not to alter its velocity parallel to the planes; but its perpendicular velocity will be materially changed. There are three cases. 1st, The velocity ES may be extinguished somewhere in X, and then the body being reflected back by the same forces, will pass off in XIMK; and we have the same phenomena as in Fig. 10. 2d. The body may pass on to CD, with a diminished velocity as at O, where taking PN=HS, but OP less than SE, the angle DON is less than the angle GEA of incidence. 3d, If the velocity be increased, then $o \rho$ being greater than SE, the angle $D o n$ will be greater. And it will be easy to demonstrate, that the sine of the angle NES of incidence, is in a constant ratio to the sine of the angle of refraction PON.

We shall now consider the mutual action of three masses, being a more general application of the system of three points. Let the three masses, of which the centres of gravity are A, B, and C, Plate LXV. Fig. 12. act on each other, with forces directed towards the centres of gravity; and first let us consider the directions of the forces. The force of the point C, when attractive on either side, as CV, Cd, will be Ce; if repulsive, as CY,

Ca, it will be CZ; and the direction, in either case, will pass through the triangle, at least when produced to the opposite parts, cutting in the one case the interior angle ACB, and in the other, the one vertically opposite. With the attractive force CV towards B, and repulsive CY from A, the resulting force is CX. The opposite supposition gives Cb, each of which keeps without the triangle, and cuts the external angle. To the first, Cz, the attractions BP and AG correspond, and these, with the attractions AE and BN, would produce the forces AF and BO; but with the repulsions AI and BR, they would produce AH and BQ. In either case the forces lie towards the same side of the line AB, and either both enter the triangle tending towards it, or both of them go away from it, and tend in a direction opposite to that of the force Ce in respect of AB. To the second, CZ must correspond the repulsions BT and AL, which, with the repulsions AI, BR, constitute AK, BS; but with the attractions AE, BN, they form AD and BM. Of these, the first pair, as well as the last, lie towards the same side of AB, and the directions of both, when produced backwards, enter the triangle, but with contrary directions to CZ; or they go away without the triangle in opposite directions from CZ. Thirdly, if CX be got, which would be produced by CV, CY, then BP and AL correspond to it, and, if the first be conjoined with BN, we shall have BO entering the triangle; but if with BR, then indeed BQ falls without the triangle as well as CX; but the corresponding forces AL and AI produce AK, which, at least, enters the triangle when produced back: wherefore there is, in every case, some one of the directions which passes through the triangle; and then what was said in the cases of Ce and Cz, returns respecting the other two. We have therefore the following theorem: If three masses act on each other, with forces directed to their centres of gravity, the compound force, acting on one at least, has a direction, which, at least, when produced towards the opposite parts, will cut the interior angle of the triangle, and enter it: The remaining two both enter, or they both avoid the triangle, and always proceed towards the same parts, in respect of the line joining the centres of the masses: And, in the first case, all the three forces tend towards the interior of the triangle, lying in the interior angles; or all tend away from the triangle lying in the vertical opposite angles: But in the second case, with respect to the line joining the two masses, they tend towards the opposite parts from that towards which the force of the first mass is directed.

Another and more elegant theorem, relating to the directions, is, that the directions of all the three compound forces, if produced both ways, will pass through the same point; and if the point be within the triangle, they tend directly all to it, or all from it; but if without the triangle, two tend directly towards it, and the third from it, or the reverse.

That all three pass through one point, is thus demonstrated: In any figure, from 13 to 18, Plate LXV. which exhibits all the different cases above mentioned, let the force of C be that which enters the triangle, and let the other two HA, QB meet in D. The force belonging to C is also directed by D. Let CV, Cd be the composing forces, and having drawn CD, let VT be parallel to CA, meeting CD in T: if it be shown that it is equal to Cd, the thing is proved, since, by drawing dT, we have dV a parallelogram. Its equality will be seen by considering the ratio of CV to Cd, as compounded of

the five ratios $CV : BP$, $BP : PQ$, PQ , or $BR : AI$; AI or $HC : C d$. The 1st, by calling A, B, C masses, of which these are the centres of gravity, is, from the equality of action and reaction, the ratio $B : C$. The 2d, $\sin. PQB$ or ABD , to $\sin. PBQ$ or CBD ; the 3d, $A : B$; the 4th, sine HAC or CAD , to sine GHA or BAD ; the 5th, $C : A$. The three ratios of the masses compose the ratio $B \times A \times C : B \times C \times A$, a ratio of equality. There remains the ratio $\sin. ABD \times \sin. ACD$, to $\sin. CBD \times \sin. BAD$. For $\sin. ABD$ and $\sin. BAD$, put AD and BD proportional to them; and for $\sin. CAD$ and $\sin. CBD$, put $\frac{\sin. ACD \times CD}{AD}$ and $\frac{\sin. BCD \times CD}{BD}$ equal to these by trigonometry; and we have the ratio $\sin. ACD \times CD : \sin. BCD \times CD$, that is, $\sin. ACD$ or CTV (equal to it sine VI , CA are parallel,) to $\sin. BCD$ or VCT , or which is the same, the ratio of $CV : VT$. Therefore $CV : C d :: CV : VT$, or $C d = VT$; and therefore $CVTD$ a parallelogram. Q. E. D.

Cor. Should two of the forces be parallel, the third must also be parallel, and the middle one has the opposite direction of the other two.

Cor. If the directions of two forces be given, the third may be found, being drawn through their point of concurrence.

Let us next compare the magnitudes of the forces—there immediately occurs this theorem: The accelerating forces of any two masses are, in the ratio, compounded of the direct ratio of the sines of the angles, which the line, joining their centres, makes with the lines joining the same centres with the centre of the third,—the inverse ratio of the sines of the angles, which the directions of the forces make with the same lines joining them to the third,—and the inverse ratio of the masses.

For BQ is to AH as $BQ : BR$, and $BR : AI$ and $AI : AH$. The first ratio is that of the sines QRB , or CBA , to the sine BQR , or PBQ , or CBD ; the second as $A : B$; the third $\sin. HIA$, or HAG , or CAD , to the $\sin. HIA$, or CAB : these ratios, changing the order of antecedents and consequents, are the ratios of $\sin. CBA : \sin. CAB$, which is the first direct ratio; $\sin. CAD : \sin. CBD$, which is the second or inverse ratio, and of the mass A to B , which is the third and inverse ratio. The demonstration is the same, if BQ or AH be compared; and in this demonstration the angles, or their supplements, having the same sines, may be taken indiscriminately.

From this proposition, a number of elegant corollaries are derived; but as they cannot easily be abridged, we refer our learned readers to the work of the author. We shall only observe, that the properties of the lever, and of the equilibrium of forces acting in the same plane, are derived with facility, independent of the usual, but unphilosophical, supposition of inflexible connecting lines, destitute of all force but cohesion. With equal ease, he derives the properties of the centres of oscillation, conversion, and percussion. But ere we take leave of this part of the subject, we cannot refrain from offering to the attention of the reader, the solution of the following problem, respecting the equilibrium of two masses connected by two other points, since all that relates to momentum and equilibrium in the lever is comprehended in it.

Let there be any number of points of matter in A , Plate LXV. Fig. 19. which call A , and any number in D , which call D . Let all these points be solicited in the directions AZ, DX , parallel to the given straight

line CF , however different may be the forces. Let there be in C and B two points, which mutually act on each other, and on the points situated in A, B , and by these actions, hinder all action of the forces in A and B , and all motion of the point B ; the motion of C being prevented by the contrary action of some fulcrum upon which it acts, according to the direction compounded of all the forces it has. Required the ratio of the sum of the forces at A and D must have to this, that the equilibrium may exist, and likewise the magnitude and direction of the force exerted on the fulcrum at C .

Let AZ, DX express the parallel forces of all the points in A and D . That these may be opposed, there should be equal and contrary forces at these points, viz. AG , and DK . These must arise from the actions of the points C and B , according to the right lines AC and AB on A , and on D according to DC and DB . Having drawn GI, GH parallel to BA, AC , it is plain that the force AG must be composed of AI and AH , of which the first repels any point in A from C , and the second attracts it to B . On account therefore of the equality of action and reaction, the point C will be repelled from A , and B will be attracted: in like manner C will be repelled from D , and B attracted. The point C therefore has two forces, one in the direction AC , and equal to IA drawn into A ; the other equal to DM into D , and in the direction CD : in like manner, B is affected by the two attractions $HA \times A$, and $LD \times D$. The force resulting at B ought to be equal, and opposite to the resulting force at C . It has therefore the direction BC , when the point C is within the angle ABC , and the reverse when without it: and to produce the equivalent reaction in CB , we must give C the two opposite forces, equal also to $HA \times A$ and $LD \times D$. Wherefore

The point of A has two forces, AI, AH .

The point of D has two forces, DM, DL .

The point of B has two forces, $A \times AH, D \times LD$.

And C four, $A \times IA, D \times MD, A \times HA, D \times LD$.

Now let the line BC express the magnitude of the force compounded of CN and CR parallel to DB, AB . BN and BR will express the magnitude of these forces as well as their directions, and therefore RC, NC , equal and parallel to them, will express the third and fourth forces of the point C . Produce AC and DC till they meet, in T and O , the lines RT, NO drawn parallel to VF, GZ , or KX , and drop the perpendiculars AF, DE, RS, NQ .

Since IAG, CTR are similar, having their sides parallel, and also CON and MDK , therefore as IG or AH , to CR or BN or $A \times AH$, (that is to say, as 1 is to A ,) so is AG to TR , and AI to TC . TR is therefore equal to GA , (or AZ ,) drawn into A , and $CT = IA \times A$. The former consequently expresses the sum of the forces AZ of all the points of A ; the latter the first part of the force of the point C , viz. $A \times IA$. For the same reason, NO will express the sum of all the forces DX of all the points in D , and OC the second force of the point C , viz. $D \times DM$. Wherefore

The sum of the parallel forces in $A = TR$.

The sum of the parallel forces in $D = NO$.

The two forces in $B = BN, BR$.

The four forces in $C = CT, OC, RC, NC$.

Now it is obvious, that the first CT and third RC compose the force $RT =$ the sum of parallel forces in A ,

and that OC and NC compose NO the sum of the like forces in D. Wherefore it is also evident, that the fulcrum C is urged by the point C alone, with a force which has the same direction as the parallel forces in A and D, and is equal to their sum; that is, it is urged in the same manner as if all the points in A and D were in the point C alone, and acting with these forces immediately on the fulcrum.

Besides, from the same parallelism of the sides we have the following triangles similar, viz. CNO and DPC; CNQ and PDE; CPR and VCN; CRS and VNQ; CVA and TCR; VAF and CRS.

These exhibit the following proportions:

$$\begin{aligned} \text{ON} : \text{CP} &:: \text{NC} : \text{PD} :: \text{NQ} : \text{DE}. \\ \text{CP} : \text{CV} &:: \text{CR} : \text{NV} :: \text{RS} : \text{NQ}. \\ \text{CV} : \text{RT} &:: \text{VA} : \text{RC} :: \text{AF} : \text{RS}. \end{aligned}$$

In which, comparing the first column with the last, we have by perturbate equality ON : RT :: AF : DE. That is, the sum of all the parallel forces in D, to which ON is equal, is to the sum of all the forces in A=TR, as the perpendicular distance AF (from the latter point to the line which passes through the fulcrum parallel to the direction of the forces) to the perpendicular distance DE from the former point to the same line. Wherefore the ratios required are now found; and we have a demonstration of the fundamental property of the lever in the commonly supposed desperate case of parallel forces.

We shall only take notice, in this place, of the mode in which the theory is applied to the pressure and velocity of fluids. Let the points lying (Fig. 20.) in any straight line AB, tend in that direction by any external force the action of which these points destroy by their mutual forces, so that they are in equilibrio. Between the first point A, and the second next it, there must be a repulsive force equal to the external force acting on A. The second point will therefore be urged by this repulsive force, as well as by its own tendency. The repulsive force between the second and third must be equal to this, and so on, increasing towards B, which will be urged forward by the sum of all the external forces of the points before it.

But if the points are not in one straight line, but dispersed throughout a parallelepiped, Plate, LXV. Fig. 21. whereof FH is the base perpendicular to, and EFHG a section parallel to the direction of the external force, it may be shown by the composition of forces, but it is sufficiently evident, that the repulsive forces with which the base acts on the particles next it, is in this case also equal to the sum of all the external forces, and this either in solids or fluids. But since the parts of a fluid are free to move in any direction, the reason of which we shall see hereafter, each particle will be pressed in every direction with the same force; so that in any plane IL, the forces are every way equal, and any particle N in LM will be urged towards FH as towards EG; and hence we see at once the reason why the base FH receives the same pressure from the fluid FLMACKH, as from the whole PEGH; and the superficies LM receives a pressure upwards from the particles N, equal to what it would receive in the opposite direction from the mass LEAM. In this way, therefore, the hydrostatic paradox, bellows, &c. admit of explanation. If to increase the repulsive force considerably, much change of distance be requisite, the compression of the mass will be sensible, and likewise the increase of density among

the lower particles; such is the case with air. If the repulsive force be powerful at small changes of distance, the mass will appear as if incompressible; which is the case with water, mercury, &c.

When a free exit is allowed to the particles of a mass of this kind, by means of an orifice, they will escape with velocities corresponding to the forces by which they are impelled. The first particle will begin to move by the repulsive force with which it is pressed by the neighbouring particles; then the second, being more distant from it than from the third, will also move away with a force corresponding to the difference between the repulsions, and therefore more slowly: the particles, therefore, will separate by the first being accelerated, until at length the repulsive force ceases, or an attraction begins, so that there will be some oscillation; but this only during a very short space of time. The velocities will depend on the area of a curve, the axis of which expresses the space passed over from the beginning of the motion. We know, that in the efflux of water the velocities are as the square roots of the heights, or compressing forces. This may be expressed by the logistic curve, as well as by many others. Whether the same absolute velocity takes place in all fluids, is matter of experiment. But we shall now proceed to the application to physics; what has been already said respecting mechanics, being a specimen of the boundless fertility of the field before us.

Application of the Theory to Physics.

In treating of the application of the theory to mechanics, we have noticed many things connected with the department on which we are about to enter. But, in order to proceed with more regularity, we shall return, in this place, to the general properties of bodies, and, in afterwards proceeding to those particular properties by which the variety of nature is explained, content ourselves with the deduction of the common principles on which their respective properties depend.

The impenetrability of bodies flows naturally from the theory of repulsive forces acting in the smallest distances, the mutual penetration of the points being thereby prevented. Besides, as the least part of space is infinitely divisible, whilst the number of points of matter in any body is finite, it is infinitely improbable that any two points should ever meet; seeing there can be an infinite number of lines for them to move in, besides that which joins them. If, indeed, there were no repulsive forces, every mass would pass freely through every other, as light through glass, &c. and yet without any real penetration; but the forces extending to some distance, hinder this free passage. Now, the curve of forces may have no asymptotic arch, except the first DE, in Plate LXV. Fig. 1. of which the asymptote is in the beginning of the abscissas. Or it may have several such arcs. In this second case, if there be any asymptote at a distance from the beginning of abscissas, which has a repulsive arc without it, and an attractive arc within, then the points placed at a nearer distance cannot pass outwards, nor those at a greater distance come nearer. And in this way we may conceive a particle, a sheet, or a wall, composed of such points which would be altogether impenetrable by any external force. But in the first case, where there is no asymptotic arc except the first, it is plain, that if a velocity sufficiently great be given to any

mass, it may pass through any other without any derangement of parts. For a certain time is requisite, in order that the forces, by their action, may produce any the smallest motion; and we may suppose this time by the swiftness of the motion to be diminished without limit. Thus, an iron ball may pass swiftly near several strong magnets, without being sensibly attracted by them, although its passage might be altogether prevented if it should move more slowly. Should the motion of the ball be not so great, it may derange some of the nearest magnets, and even carry them away with it, although the others at a greater distance be not sensibly affected. Thus, a ball from a gun passes through a plank of wood without deranging any part but that which lies before it, though it would break all the neighbouring parts if its motion were slower. And it is probably the vast *velocity of light* which carries it through pellucid homogeneous space, without any compenctration or derangement of its rectilineal motion.

From impenetrability arises physical extension: For, since the points of matter cannot occupy the same place, they must necessarily be posited without each other; and since they cannot be in absolute contact, they must be separated by some space, however small, not all in one line or plane, but diffused in space, extended in length, breadth, and depth, although so near each other that the interval escapes our senses.

From extension arises figurability, since the space throughout which the points are dispersed has its limits, upon which its figure depends. The figure, however, of those bodies which fall under our notice can never be accurately defined, on account of the inequalities of all surfaces; but we take, in a vague and indistinct way, that figure which seems to approach nearest to the true form. Thus, we say the world is a globe, or a flattened spheroid, although the roughness of its surface makes it very different indeed from either the one or the other. From figure arises bulk, which is nothing more than the whole space in length, breadth, and thickness, which is inclosed within the external surface, and therefore our idea of it must be equally vague with that of the figure. The mass of a body is the whole quantity of matter, or, according to Boscovich, the number of points belonging to it. Our ideas of mass are yet more vague and indeterminate than those of bulk or figure; for it is not clear what must be excluded when we take only the matter belonging to a body. For all bodies are composed of very heterogeneous parts, as is evident from ocular inspection, as well as chemical analysis. Some exclude from the mass of bodies that very fine ether, much rarer than air, which they suppose interspersed throughout space; and even the air which occupies the pores of most bodies, is considered as forming no part of them. The water and air are no part of the sponge; but who considers the blood and juices as forming no part of the animal, or the sap as no part of the living tree: And air has been shown to exist fixed in many bodies, and essentially contributing to their constitution and properties. It is evident, therefore, that our notion of the mass of a body is, as yet, but arbitrary and rude.

Density, is the relation of the bulk to the mass, and is greater when the mass is greater in the same bulk. Hence the measure of density is the mass divided by the bulk. But this theory differs from the common opinion, as we have already seen, in supposing that there can be no limit to the density of bodies, since the points of mat-

ter may approach to each other indefinitely near, or may be removed to an indefinite distance.

The inertia of bodies arises from the inertia of the points, and their mutual forces: For having demonstrated, that the centre of gravity of any system is either at rest, or moves uniformly in a straight line, undisturbed by the mutual action of the points composing the system, it is plain, that the same thing must take place in all bodies; and the *vis inertiae* consists in nothing else, being the determination of continuing in the same state of rest, or uniform motion.

Mobility is a consequence of the curve of forces, which, expressing by its ordinates the determinations to access or recess, necessarily implies mobility, or the possibility of motion. Some have mentioned quiescibility, or the capability of being at rest, as a property of matter. Boscovich thinks it does not exist in nature, at least as at present constituted; and he endeavours to demonstrate the truth of this sentiment, by arguments drawn from the nature of infinities, and the law of continuity. He proceeds next to the consideration of the law of equal action and reaction, which had been already proved in the second part.

Divisibility is assumed by many as a property of matter, and, with respect to continued space, infinite divisibility is undeniable; but, when we consider matter as made up of a finite number of points, the divisibility has evidently a limit; for, if we suppose it carried so far as that the intervals are less than the distance between the points of matter, subsequent sections will divide not matter but empty space. But although there be no divisibility *in infinitum*, according to our author, yet there is what he calls compossibility, which answers the same purpose: That is to say, between any two points of matter there may be interposed a third, another between this new one and each of the first; and so on without limit. So that, within a given space, however small, there may be such a number of points as if distributed throughout a greater space, may leave no cubic space so small as to be altogether free of matter.

Universal gravity, at all sensible distances, is also a part of our theory; and perhaps the curve of forces, after extending to the utmost limits of our planetary and cometary system, may intersect the axis, and pass to repulsion. This would obviate the objection made to the Newtonian doctrine of attraction, that the planets, stars, and all matter, must be thereby at length condensed into one mass. If such a repulsion takes place, the curve may even wind again about the axis, and form limits of cohesion. And in this way it is possible that our sun, with all the fixed stars, may form a particle of an order superior to those which compose our system, and belonging to a system vastly greater.

From gravitation we proceed to cohesion, which has never been so well explained as by the theory of Boscovich. It arises immediately from the limits of cohesion, of which we have already treated in the first part of that article, and, therefore, we need not here enlarge upon it.

We proceed now to the particular properties of bodies, by which the infinite variety of nature is accounted for. And here the variety offered to us by the theory is indeed immense: For, in the first place, there may be different numbers of points constituting particles of the same bulk; then the bulks may vary so, that no two particles have the same bulk, mass, or density; or, these being the same, the figure may be infinitely varied; and the points may be altogether placed towards the exte-

mor surface, or dispersed throughout the mass; or of different densities in different parts of the particle. And great as may be the variety in the number and distribution of the points, the variety in the mutual forces of the particle is still more unlimited.

The parts of fluid bodies are easily separated from, and moved among, one another. This seems owing to their being spherical and homogeneous. Their forces are in a great measure directed to their centres. They are therefore at liberty to be moved round each other, and will yield in any direction to a very small force. Between the particles of some there is very little, if any attraction, as in sand, dry powders, and seeds, which approach much to fluidity; others have a sensible attraction, as water, or, more perceptibly, mercury, and the like, since they form themselves into drops; in a third sort, as air, there is a powerful repulsion, and, unless confined, they will dilate themselves to a great extent; the particles must therefore be not in limits of cohesion, but in a repulsive arc of the curve expressing their forces.

When the figure of the particles recedes much from being spherical, or the distribution of the points is unequal, the free circular motion cannot take place, and the consequent lateral forces will produce all the phenomena of solidity. Thus, if two parallelepipeds be situated beside each other, and in some limit of cohesion, the one cannot move away without bringing the other with it by the increasing attraction, or move towards the other, without pushing it before it by the increasing repulsion. And if it be any way inclined, the other parallelepiped will be attracted on one side, and repelled on the other, and of course will follow the inclination of the first. A continued series of parallelepipeds will form a long fibre, or a solid rod, of which if the base or end be inclined, the whole will follow. The same is true of all other figures, however unequal.

If the limits in which the particles are situated be powerful, the bodies will appear hard and inflexible; but soft and flexible, if these limits be weaker. If the arches of attraction and repulsion do not extend far on either side, the particles may come in flexure to new limits, and remain without any effort to recover their shape, as lead, and other ductile bodies. If the arches be very small, and if after that no action or a repulsion take place, the body is fragile, or brittle. If the arches be longer, the same force will continue to act, and bring back the body to its former position; nay, in consequence of the accelerated motion, the parts will pass their former positions, and vibrate backwards and forwards, by which means we account for elasticity.

Viscous bodies occupy the mean between solids and fluids; having less cohesion than the one, and more than the other. Besides their mutual tenacity, they have a force of attraction, whereby they stick to other bodies, and moisten them. This humidity is relative. Water will stick to some bodies, and is expelled by others.

The composition of crystallized and organic bodies appears very wonderful. But if we consider that particles may be so formed as in certain parts of their surfaces to attract certain other particles, in others to repel them, it is easy to conceive how they may only coalesce in certain peculiar figures; and in this way secretion, nutrition, and vegetation, may be equally explained.

The resistance of fluids to bodies in motion arises partly from the motion impressed on the particles of the fluid, since, according to the laws of collision, the

body impressing a motion on another will lose some of its own. It also arises partly from the forces exerted by the particles against those which obstruct their motion. To define accurately the laws of resistance, is a matter by no means easy. We should know the law of forces, the number and disposition of the particles. And after all the problem would be too complicated for our analytical skill. But it may be generally observed, that, in so far as it arises from the inertia of the fluid itself, the resistance is as the density and square of the velocity jointly. As the density, because with an equal velocity, the resistance will be as the number of particles moved. As the square of the velocity, because the number of particles moved will be as the velocity, and the motion impressed on each will be also as the velocity. The resistance arising from the mutual forces of the particles will be constant, or as the times only, if these forces be equal in all the particles; but as a greater velocity will produce a greater compression among the particles, and of course produce greater mutual forces, the resistance, therefore, is partly constant, and partly also in some ratio of the velocity. And with this, experiments appear pretty well to agree.

The principles of chemical operations are all deducible from the same source, namely, from the variety of the particles. Were they subjected to the observation of our senses, there might, without doubt, be a general reason given from the theory, for every chemical operation. But for this would be required an intimate knowledge of the texture of every particle, and its disposition in the general mass; and a skill in geometry and analysis, which far exceeds the powers of the human mind.

Some of these phenomena may be explained as follows. The particles of some solids have a less attraction for each other, than for those of some fluids. Hence these particles are separated, and surrounded on all sides by the fluid. The mixture is therefore composed of globules and retains its fluidity. In this way we may have an idea of *solution*. But as the attractive force will cease at a little greater distance, the solid particles will only be covered to a certain depth; and the fluid is then said to be *saturated*. If another substance, whose particles are more attracted by those of the fluid, be introduced into the mixture, the particles which had been conglomerated round the former, will be drawn away and accumulated round those of the latter, which will be dissolved in their turn; while the former by its natural gravity, falls down in a fine powder. This is called *precipitation*; and perhaps rain is a precipitation of this kind, when the aqueous particles are abandoned by the air. The combination of two fluids frequently forms a solid; and it is often observed that the specific gravity of the compound is greater than the mean, or its mass less than the sum of the component substances. This may be explained by supposing that the particles, in the first case, come into limits of cohesion; and that in the other, by being attracted more strongly, they come into smaller distances. When a solid is combined with a solid, it is necessary to dissolve, or reduce one of them to powder, so that their small particles may approach to and join each other. This is principally done by fire, which, by its vehement agitation, and the intestine motion of its particles, may account for the phenomena of fusion, liquefaction, and volatilization. By this violent agitation, our author proceeds

to account for several other of the phenomena of chemistry, such as fermentation, effervescence, and the like. But the reader acquainted with modern chemistry will put little value on such explanations as this. The facts at that time known were too few, or too imperfectly described, to enable him to found a permanent theory. And we have since seen many others fail in perfecting the same structure, who had more numerous materials than Boscovich.

Fire he conceives to be a sort of fermentation, which chiefly, if not solely, takes place in sulphureous matter, when it meets with the matter of light in sufficient abundance. This agitation separates the parts of other bodies, and brings their particles into new spheres of action, by which a small spark may speedily propagate the motion throughout a great mass; as the foot of a small bird alighting on the top of a precipice, may move the sand, and that the gravel and stones below it, until at length great rocks, towards the bottom tumbling into the sea, may produce a wide and lasting agitation. In the same manner, if the limits of cohesion of any body, be succeeded by a powerful repulsive arc, the small motion produced by a foreign body, may make some or all of the points pass the limits of cohesion, and be repelled from each other with great force and velocity; so that a volatilization may take place—a deflagration, or sudden explosion.

Light may be a sort of very fine fluid, or a kind of vapour thrown off by vehement fiery fermentation. Its celerity may be accounted for, by supposing the repulsive arcs sufficiently powerful: its rectilineal propagation, by its great velocity, which affords little time for the forces of the points to produce any sensible effect; and also by the equality of actions on all sides, in a medium which is homogeneous. This homogeneity accounts for the free passage through pellucid bodies; whereas opacity will arise from the unequal texture of heterogeneous particles producing unequal forces, which, acting on the light in various directions, inflect it in various ways; and, if the substance be somewhat thick, totally prevent its passage. The other phenomena of light may be explained in equal conformity with the principles of the theory, as is done by our author, with great acuteness and ingenuity.

He next proceeds to our bodily sensations of taste, sound, smell, and feeling. He explains these much in the usual way, excepting, that for the immediate contact of bodies, or of the particles emitted, he substitutes the attractions and repulsions, or oscillations of the particles; which, indeed, are particularly well fitted for causing that motion in our nerves, which the disciples of Hartley have supposed to take place in the organs of sensation. But, indeed, we do not see how any attempt to account for these should have been introduced into his theory.

In explaining the phenomena of electricity, he adopts the theory of Franklin respecting a peculiar fluid, which, by its transference and constipation, produces the attractions, repulsions, sparks, &c. and even lightning and thunder.

As to the phenomena of magnetism, they may be all reduced to the attractions of certain substances for each other. Perhaps they also may be owing to the intervention of some peculiar effluvium; but, in either case, they are sufficiently reconcilable with the principles of the theory.

Finally, it may be observed, that although the first elements of matter are said to be indivisible, inextendible, endued with the *vis inertiae*, and the mutual forces expressible by the curve, so often alluded to; yet whether this law be intrinsic and essential to those elements; whether it be something added to them, as the substantial and accidental forms of the Peripatetics; or whether it be the free law of the Author of Nature, chosen at will for the direction of these motions, as may be more agreeable to the Cartesian; we do not here enquire, nor in truth can it be learned from the phenomena which opinion is the most correct. The theory may be employed in any of these modes of philosophising, and fitted to the peculiar turn of thinking in each.

We intended to have concluded this article with a few general observations on the theory of Boscovich; but as we shall have occasion to resume the subject under the head of CORPUSCULAR PHILOSOPHY, these observations may be introduced with equal propriety, and with more effect, in that part of our work. (A. N.)

BOSJESMANS, or BOSHIES-MEN, the name of a savage people who inhabit an extensive district in the colony of the Cape of Good Hope. They are called Bosjesmans, or men of the thicket, from their lurking among the bushes, in order to shoot travellers with their poisoned arrows. The Dutch colonists, who often suffer from the rapacity of this people, treat them with the severest retaliation. They fire at them as if they were wild beasts; and Mr Barrow heard one of the colonists boast, that he had shot with his own hands nearly 300 Bosjesmans. Those who are taken alive, in any of their predatory excursions, remain during life in a state of servitude.

While the Bosjesmans are engaged in their plundering expeditions, their haunts are in the kloofs or chasms excavated by torrents of water, that wash down the steep sides of the high stratified mountains. A succession of caverns is thus formed, the highest of which is chosen

by the Bosjesmans as the most difficult to surprise. In one of their retreats, which was visited by Mr Barrow, he observed drawings of several animals, executed with great force and spirit, upon the smooth sides of the caverns. The materials which were used were charcoal, pipe clay, and different kinds of ochres. A black substance, resembling pitch, or rather Spanish liquorice, formed a thick coating upon the upper surface of the cavern. It had a bituminous smell, flamed weakly in the candle, gave out a thin brownish fluid, and left a black coally residuum about two-thirds of the original bulk. It is said to be deadly poison, and to be used by the Hottentots for poisoning their arrows. The Bosjesmans live together in small hordes or kraals, consisting of a number of separate huts, each of which is made of a small grass mat, bent into a semicircular form, and fixed down between two sticks. These huts are only about three feet high, and four feet wide, and are open

before, and closed behind with a second mat. The mould within the hut is excavated like an ostrich's nest; and a little grass strewed in this simple hollow, serves for the bed in which the Bosjesmans lie coiled round like some of the lower animals. In one of the kraals which Mr Barrow saw, there were 25 huts, and about 150 inhabitants.

Bigamy seems to prevail among the Bosjesmans. The elderly men have two wives, one that is young, and another that is past childbearing; and no degree of consanguinity prevents a marriage, unless in the case of brothers and sisters, and parents and children.

The men go completely naked, and the women have only a small belt of springbok's skin, having the fore part cut into loose threads, which, though perhaps intended for a covering, did not answer the purpose. The men had pieces of wood, or a porcupine's quill, suspended to the cartilage of the nose; and some of the women had caps like helmets, made of ass skins, and shells, beads, or bits of copper, hanging on their necks from their curling tufts of hair. In person, the Bosjesmans are extremely diminutive. The tallest of the men was only 4 feet 9 inches high, while the tallest woman measured only 4 feet 4 inches. Though they have a general resemblance to the Hottentots, yet they are greatly inferior to them in personal appearance, and seem to be the ugliest of all the savage tribes. Their high cheek bones, flat nose, prominent chin, concave visage, and sharp rolling eyes, resemble those of the ape tribe; and the upper eyelid is so rounded into the lower on the nasal side of the eye, that it does not form an angle. The protuberance of their bellies, the projection and size of their posteriors, and the great curvature of their spine, though characteristic, in some degree, of the whole Hottentot race, belong, in a still greater degree, to the Bosjesmans. "If the letter S," says Mr Barrow, "be considered as one expression of the line of beauty, to which degrees of approximation are admissible, the Bosjesman women are entitled to the first rank in point of form. A section of the body, from the breast to the knee, forms really the shape of the above letter. The projection of the posterior part of the body in one subject, measured five inches and a half from a line touching the spine. This protuberance consisted of fat, and when the woman walked had the most ridiculous appearance imaginable, every step being accompanied with a quivering and tremulous motion, as if two masses of jelly were attached behind." It is a woman of exactly this description, that has been for some time exhibiting in London under the name of the *African or Hottentot Venus*.

But though the general figure of the Bosjesmans is remarkably distorted, yet their limbs are well turned and proportioned, and their activity is truly astonishing. They leap from rock to rock with the velocity of the antelope, and horsemen cannot overtake them on rough ground, or along the sides of mountains. In order to give them additional speed, they push the testicles to the upper part of the root of the penis, where they remain as firmly and securely as if it had been their natural position.

The Bosjesman women possess another peculiarity of a very singular nature. The nymphæ are in all of them elongated, and in some of them, examined by Mr Barrow, the elongation exceeds five inches, though in others it is said to be much longer. These projecting labia collapse and hang down, and appear, at first sight, to be

a masculine organ. Their colour is livid blue inclining to red, not unlike the excrescence on the beak of a turkey. This deformity is said by some travellers to be produced artificially, by suspending pieces of stone from the internal labia; but there are numerous instances of its being possessed by Bosjesman women, who have been taken from their mothers when infants, and brought up with the Dutch farmers. This elongation of the nymphæ is found in all Hottentots, seldom exceeding three inches and appearing only like a projecting orifice, or elliptical tube an inch long. In the children of a European and a Hottentot this deformity ceases to appear.

Though the Bosjesmans are completely Hottentots, yet, in the bent and energy of their minds, they differ widely from those who live in the colony. Lively, cheerful, and active, they hate to be idle, and are always employed in some active occupation or amusement. During the day they are generally confined to their huts, lest they should be surprised by the Dutch colonists; and they often dance by moon-light from the setting to the rising of the sun. They hail the approach of the first thunder-storm, at the end of winter, as the harbinger of summer, and, animated with joy, they tear in pieces their skin coverings, and dance for several nights in succession.

There are few savage tribes whose physical condition is more unfavourable to this natural cheerfulness of mind, than that of the Bosjesmans. They neither breed cattle, nor cultivate the ground, and they have few vegetable productions that can be used as food. The bulbs of the iris, and a few gramineous roots of a bitter taste, which are found by scratching the surface of the plains, are the only vegetables which they can obtain. The larvæ of ants, and those of locusts, are the animal productions on which they subsist. They exhibit great ingenuity in taking them, but all their dexterity is often insufficient to ensure success.

At some particular seasons, these precarious sources of subsistence completely fail them, and they are compelled, by the strongest principle of their nature, to undertake a hazardous expedition into the colony for plunder; and in these excursions they exhibit a ferocity of character which does not naturally belong to them, but which has been created and inflamed by the barbarous treatment which they have received from the Dutch. "Should they seize a Hottentot," says Mr Barrow, "guarding his master's cattle, not contented with putting him to immediate death, they torture him by every means of cruelty that their invention can frame; as drawing out his bowels, tearing off his nails, scalping, and other acts equally savage. Even the poor animals they steal are treated in a most barbarous and unfeeling manner: driven up the steep sides of mountains, they remain there without any food or water till they are either killed for use, or drop for want of the means of supporting nature.

When a horde is surrounded by the farmers, and little chance is perceived by them of effecting an escape, they will fight it out most furiously so long as a man shall be left alive. It frequently happens on such occasions, that a party will volunteer the forlorn hope, by throwing themselves in the midst of the colonists, in order to create confusion, and to give to their countrymen, concealed among the rocks or in the long grass, at the expence of their own lives, an opportunity of exercising more effectually their mortal weapons upon

their enemies, and at the same time to facilitate the escape of their wives and children.

Their plundering expeditions are conducted not without system. If in carrying off their booty they should chance to be pursued, they always divide; one party to drive away the cattle, while the other continues to harass the pursuers; and when the peasantry prove too many for them, they stab and maim, with poisoned weapons, the whole herd. On all such plundering expeditions, they carry, in addition to their bows and arrows, lances that resemble the Kaffir's *hassagai*, but of a much smaller size, and always dipt in poison. Their bows are remarkably small; and, in the hands of any one but of a Bosjesman, would be entirely useless. From their earliest infancy they accustom themselves to the use of the bow: all the little boys who came to us at the Kraal, carried their bows and small quivers of arrows. A complete quiver contains about 70 or 80, made like those of the Hottentots; and, in addition to these, a few small brushes to lay on the poison; pieces of iron, red ochre, leg bones of ostriches cut in lengths and rounded, and two little sticks of hard wood to produce fire: This is done by placing one horizontally on a piece of withered grass, and whirling the other vertically between the hands, with the point acting in a hollow place, made in the surface of the former. In a few seconds of time, the velocity and friction set the grass in a blaze."

When the Bosjesmans succeed in capturing a herd of cattle, they are slain in such numbers, that vultures are attracted by the putrefying mass which surrounds their kraals; and these birds of prey are thus frequently the means of pointing out to the colonists the haunts of the plunderers.

The Bosjesmans have a singular remedy for diseases of every kind. From the belief that the disease is carried off by the effusion of blood, they take off the extreme joints of the fingers, commencing with the little finger of the left hand, as the least useful. They bury their dead, and load the grave with heaps of stones.

The language of the Bosjesmans is the same as that of the Hottentots, though they differ extremely in their mode of speaking it. The Hottentots generally pronounce one syllable of every word by the action of the tongue against the roof of the mouth, or the teeth; while the Bosjesmans pronounce every syllable in the same manner, but with a more forcible utterance. See Barrow's *Account of Travels into the Interior of Southern Africa*, 4to, p. 84, 234, 275, &c.; and Sparrman's *Voyage to the Cape of Good Hope*. (q)

BOSNIA, a province of European Turkey, derives its name from the river Bosna, which passes through it, and falls into the Save. It is about 120 miles long, and 72 broad; and is bounded on the north by Slavonia, from which it is separated by the Save; on the east by Servia, from which it is separated by the Drina; on the west by Croatia and Dalmatia; and on the south by Albania. Bosnia is a mountainous province. The arable land on the banks of the rivers produces good wheat; and the mountains afford excellent pasture to numerous herds of cattle, and are enriched with several silver mines. Bosnia carries on an inconsiderable commerce with Slavonia at Brod, on the banks of the Save, where there is a chamber of health for the merchandise and the merchants that come from Turkey. The principal articles exported by the Bosnians to Brod, are, raw skins, wool, and cotton. Besides Brod, there are several small ports upon the Save where the Bosnians

exchange their cattle, which they swim across the river, for the productions of Slavonia. A fair is held at these places every week, under the superintendance of a customhouse officer. The Bosnians import also a small quantity of wine from Slavonia. In 1802, it amounted only to 19 barrels and a half. In 1802, 168 barrels of *slivowitza* was imported into Bosnia.

The capital of the province is Banjaluka, which is the residence of a Beglier bey. The Latin bishop of Bosnia resides at Diakevar, in Slavonia.

The part of Bosnia which borders on the right bank of the Save, belonged to the house of Austria; but they lost it by the peace of 1739. In 1789 and 1790, they reconquered a considerable part of the province; but it was restored to the Turks in 1791, by the treaty of Sistovia.

The principal inhabitants of Bosnia are Greek Christians, and a few Mahometans, Jews, and Catholics. See Demian's *Tableau Geographique et Politique des Royaumes de Hongrie, D'Esclavonie, de Croatie, &c.* Paris, 1809, tom. ii. p. 54, 55, 56. (n)

BOSPHORUS, from βους an ox, and πορος a passage, is a name given to a streight by which two seas communicate with each other; but applied particularly to the streights of Constantinople, or the Thracian Bosphorus, which joins the sea of Marmora with the Black Sea; and also to the streights of Caffa, in the Cimmerian or Scythian Bosphorus, which joins the sea of Azof with the Black Sea. These streights are supposed to have obtained this name from their being so narrow that an ox could easily swim across them. Tournefort is of opinion, that the Thracian Bosphorus was so called from the cattle market being held near it. According to Olivier, the Thracian Bosphorus is about 21 miles long, and about 20 miles from the Cyanean isles, at its entrance into the Black Sea, to the point of the Seraglio of Constantinople. Its greatest breadth does not exceed two miles. The Cimmerian Bosphorus is about four leagues broad. See Tournefort's *Voyage au Levant*, tom. ii. lett. 12 et 14; Olivier's *Voyage, &c.*; and Dureau de Lamalle, *Geographie Physique de la Mer Noire, &c. passim*. See also, BLACK SEA. (j)

BOSSIÆA, a genus of plants of the class Diadelphia, and order Decandria. See BOTANY. (π)

BOSSINEY, TREVENA, or TINTAGEL, an ancient borough of Cornwall, partly situated on an isthmus, and partly on an island which was once joined to the main land by a bridge. De Maton describes it as a miserable groupe of about 20 cottages, though possessed of all the privileges of a chartered borough. The surrounding country is bleak and rugged. Near Bossiney are the ruins of a castle, in which king Arthur is said to have been born. See Osgfield's *History of the Boroughs*. (j)

BOSSUET, JACQUES BENIGNE, a celebrated French divine, was born at Dijon on the 27th of September, 1627, of a family of great respectability in the parliament of Burgundy. The talents which he displayed in the commencement of his studies, rendered the Jesuits, his first instructors, anxious to enlist him into their society; but their design was immediately perceived by an intelligent uncle, who had the charge of his education, and who, to rescue his nephew from that factious and intriguing order, sent him to Paris to finish his studies at the college of Navarre.

As his views were directed towards the clerical profession, he pursued, with the ardour and emulation of a rising genius, every study which appeared to be essen-

tial, or even remotely conducive, to his excellence as a minister of the gospel. He perused the sacred writings in particular, with a relish and fondness approaching to passion; he studied with assiduous attention, the writings of the fathers, among whom Augustine was his principal favourite; and he enriched his mind with all the treasures of classical literature. The sublime, the bold, and unconstrained effusions of the Mæonian bard, while they called forth the kindred qualities of his own mind, inspired him with a kind of affectionate reverence; he dwelt with great delight on the eloquent declamations of Cicero, and the graceful strains of Virgil; but with a sternness that does more honour to his conscience than to his taste, he condemned the fascinating, though often licentious, verses of Horace; nor could the enchanting gaiety of the poet's fancy, and inimitable felicity of his expressions, compensate, in the rigorous judgment of Bossuet, for the lax morality of the Epicurean.

The same austerity of disposition led him to disapprove the liberty frequently taken by Christian poets, of introducing into their verses, the names of heathen divinities, and allusions borrowed from Pagan mythology. We are not certain whether we should be as much alarmed as Bossuet, by the fancied immoral tendency of such a practice; but we have no hesitation in joining him, even against the authorities of D'Alembert and Boileau, in the condemnation of an abuse, which serves only to introduce absurdity into modern poems, without adding, in any respect, to their interest. A poet of genius cannot need the aid of these mythological fictions; and when they are interwoven into the flimsy productions of an ordinary versifier, they only attract attention to that indigence of thought, which they cannot conceal.

Mathematics was almost the only science which Bossuet disregarded; from a strange opinion, that a knowledge of mathematics was either useless to the divine, or directly hostile to the feelings which he ought to cherish, and the studies which he ought to pursue. Though averse to this study, Bossuet entered, with considerable eagerness, into the speculations of philosophy. The Cartesian system, which had been recently divulged, and which was then forcing its way against inveterate prejudices, recommended itself, by its boldness and its novelty, to his vigorous and independent mind; and he warmly patronized and defended it, against the fulminations of his ecclesiastical brethren, and the more formidable edicts of civil authority.

His talents for eloquence, to the improvement of which all his studies were directed, were admirably displayed from the pulpit, at the early age of sixteen. He had been announced as a young man of premature genius, at the Hotel de Rambouillet, to which merit of every kind was then summoned to appear. A numerous and select company met for the purpose of deciding on his qualifications as an orator, and proposed to him a subject, from which Bossuet, almost without preparation, pronounced a sermon, which drew forth the warmest applauses from his auditors. He had the merit of producing a total change in the tone of pulpit eloquence; and of substituting, for the coarse indecencies and quaint affectation by which it was degraded, the strength and dignity which become the sublime truths and elevated morality of the gospel. "One of those men," says D'Alembert, "who make a parade of believing nothing, wished to hear, or rather to brave him.

Too proud to own himself overcome, but too just not to pay homage to a great man; 'There,' said he, on leaving the church, 'is the first of preachers for me; for he is the person by whom I feel that my conversion would be effected, if it were to be effected at all.' Thus applauded as an orator, Bossuet became ambitious of distinguishing himself in the field of theological controversy. With this view he undertook the refutation of the catechism of Paul Ferry, a Protestant minister, with whom he had hitherto lived in intimate friendship; and it deserves to be recorded, to the immortal honour of both, that the heat of their theological contentions never betrayed them into even a momentary oblivion of their former amity. The reputation of Bossuet soon reached the court, and he was invited to Versailles, the proper theatre for the display of his brilliant talents. Amidst the splendour and seductions of a palace, he preserved a dignity and independence of conduct becoming his character as the ambassador of Heaven. Without a single effort to force himself into notice, except by his exhibitions in the pulpit or at the altar; without once descending to the meanness of flattery or paltry intrigue, he obtained from Louis XIV. the bishopric of Condom—a just tribute to his transcendent, though unobtrusive merit.

The French Academy, desirous of appropriating to themselves part of the reputation of so celebrated a man, admitted him into their number, in 1671. About the same time, he was selected by Louis as the most proper person to be intrusted with the important charge of the Dauphin's education. That he might be enabled to devote himself entirely to this sacred charge, he resigned his bishoprick, and received, in exchange, an abbacy of trifling revenue, but sufficient to satisfy his moderate desires. Aware that religion alone can furnish any restraint on the caprices of an arbitrary monarch, Bossuet made it his principal care to inspire his pupil with a habitual regard to the King of kings, whose vigilant eye observes our minutest actions; and at whose impartial tribunal sovereigns, as well as their subjects, must account for the use which they have made of the advantages with which His providence has favoured them. He composed, for the use of his royal charge, *A Discourse on Universal History*, which is certainly the most important of all his works. "In this grand sketch," we again borrow the words of D'Alembert, "we admire a genius as vast as profound, which, disdaining to dwell on frivolous details, so dear to the crowd of historians, sees and judges at one glance, Legislators and conquerors, kings and nations, the crimes and virtues of men; and traces with a rapid but expressive pencil, time, which devours and engulphs every thing,—the hand of God on human grandeur; and kingdoms, which die like their masters."

When he had completed the education of the Dauphin, Louis testified his satisfaction with his talents and fidelity, by appointing him first almoner to the Dauphiness, and investing him with the bishopric of Meaux. In this new situation, he again devoted himself to the service of religion, and the defence of the church. The numerous controversies in which he became involved with infidels and Protestants, gave him an opportunity of displaying much logical acuteness and dexterity of argumentation; he is said to have brought back to the Catholic faith, several who had embraced the Protestant religion; and such was his anxiety to effect a reunion of the Protestants with the church of Rome, that he

made a voluntary offer to travel, for this purpose, into foreign countries. With the same view, he established a correspondence with the celebrated Leibnitz; who, more tolerant or more indifferent than Bossuet, wished to restore unity and peace by mutual concessions. Bossuet remained inflexible, and insisted that the Protestants, as a preliminary step, should implicitly submit to every thing required by the council of Trent. In justice to his character, however, we must observe, that, though thus zealous in the cause of Popery, he never gave the slightest countenance to the persecution of the Protestants; persuaded that argument, and not the sword, is the proper instrument of conversion.

While he thus stood forth as the champion of his religion, he was no less strenuous in defending the particular rights of the French church, and the independence of the French crown, against the presumptuous claims of pope Innocent XI. His holiness held out to him the temptation of a cardinal's hat, in order to induce him to withdraw his opposition; but Bossuet, true to his brethren and his king, refused an honour, which, without increasing his respectability in the church, could only add the sounding title of *Eminence* to his name.

The reputation of Bossuet was now at its height; and we wish, for the honour of his memory, that we could here close the list of his theological contests. Unfortunately, he thought himself obliged to oppose, with a degree of harshness and severity for which we can find no apology, the amiable and virtuous Fenelon, who entertained some notions on Quietism, which alarmed the orthodoxy of this zealous guardian of the true faith. We are afraid that something like envy may have prompted that asperity of censure which extorted from the mild archbishop of Cambrai a reluctant complaint; and whatever might be the result of their dispute, we believe there is not one of our readers who would not have resigned all the triumphs of Bossuet, for the more honourable testimony given to his rival: Bossuet, it was observed, proves religion; Fenelon makes us love it. Yet, however we may condemn the relentless vigour of his temper, it is impossible not to respect his sincerity and firmness. When Louis, astonished at the impetuosity with which he inveighed against Fenelon, asked him, "What would you have done, if I had taken part with Fenelon against you?" "Sire," replied the spirited bishop, "I would have cried twenty times louder." On another occasion, however, he showed a more temporising disposition: for when Louis, who was passionately fond of theatrical entertainments, which Bossuet had uniformly condemned, consulted him with regard to the propriety of going to a certain play, "Sire," replied he, "there are great examples for it, and strong reasons against it."

From these scenes of bustle and contention, we accompany Bossuet, with much satisfaction, to his own diocese; where, forgetting the tumult and vanity of the world, he devoted his whole time to the instruction of the ignorant, the support of indigence, and the consolation of misfortune. "It was a rare and affecting spectacle," says his panegyrist, "to see the great Bossuet, transported from the chapel of Versailles to a village church, instructing the peasants to bear their evils with patience; assembling with tender affability, their young family around him; taking pleasure in the innocence of the children, and the simplicity of the parents; and

finding in their naiveté, their movements, and affections, that precious truth which he had sought for in vain at court, and so rarely met among men." Amidst these labours of love, he tranquilly closed his life, on the 12th of April 1704, regretted by the whole Catholic church, which still reveres his memory as one of her ablest and most faithful champions. Different colleges vied with each other in the funeral orations which they pronounced in his praise; and his grave was bedewed with the unfeigned tears of the flock, whom he had guided by his example, and soothed with the affectionate care of a father.

Of the merit of Bossuet, as a preacher, it is not easy to form a fair estimate; for, as he seldom wrote more than the heads of his discourse, the sermons which he has printed must be regarded rather as bold and hasty sketches, than finished compositions. In his funeral orations he is altogether unrivalled, for elevated sentiments and affecting tenderness. The most celebrated of his funeral orations are those pronounced in honour of the queen of England, widow of Charles I.; the duchess of Orleans, sister to Charles II.; and the celebrated prince of Condé. (k)

BOSTON, formerly *Botolph's Town*, a large commercial town of England, in Lincolnshire, situated on the east side of the river Witham, about five miles from the sea. The town is well built, and has lately received very considerable improvements. Its spacious market-place is adorned with a handsome cross, and a commodious assembly room. The public buildings are the theatre, the fish market, built in 1772, and the elegant church of St Botolph's. This magnificent building was begun in 1309, and is said to be the largest parochial church, without cross aisles, in the world. Its lofty tower, which is 232 feet high, supports an octagon lantern which serves as a lighthouse to the vessels that navigate the dangerous channels of Lynn Deeps and Boston Deeps. It has 365 steps, 52 windows, and 12 pillars, corresponding to the number of days, weeks, and months, in the year, and is 300 feet long, and 100 feet wide.

Boston formerly carried on a great trade in the exportation of wool, but after this trade was prohibited, it carried on a considerable foreign and coasting trade. At spring tides, the Witham is navigable for vessels of about eleven feet of water, and the barges navigate this river as far as Lincoln. Some of the foreign vessels trade in timber, rye, wine, &c. and several ships are employed in the corn trade to London.

The fens with which this town was formerly surrounded, have been, in a great measure, enclosed and drained, and form good meadow and arable land. It is proposed to build an iron bridge over the Witham, instead of the present wooden one. Number of houses 1221. Population in 1801, 5926, of whom 866 were returned as employed in trade and manufactures. See Oldfield's *History of the Boroughs*, and Howlett's *Select Views of Lincolnshire*. (j)

BOSTON, called *Shaumut* by the Indians, and *Trimountain* by its first settlers, is a large town of America, the capital and port of the state of Massachusetts and of New England, and the third town in point of size in the United States. It is situated on an irregular peninsula at the bottom of Massachusetts bay, and is connected with the main land by an isthmus, at the south end of the town. The length of the town, including the rock, is three miles, and its widest part one mile and

139 yards. The town of Boston contains 79* streets, 36 lanes, 26 alleys, and 18 courts. The principal public buildings are, the State-house, the court house, two theatres, Faneuil hall, concert hall, the almshouse, the workhouse, the powder magazine, the gaol, and the bridewell; besides 19 buildings for public worship, most of which are adorned with lofty and beautiful spires. On Beacon Hill, the highest land in the peninsula, is a monument, having on its top a gilt eagle, and the arms of the union, with several inscriptions on its base, in commemoration of the leading events of the American war. On the south side of the hill, a magnificent statehouse was begun in 1795; and on the east side is the Mall, which is a delightful promenade about 600 yards long, adorned with rows of trees. The two bridges over Charles River, called Charles River Bridge, and West Boston Bridge, contribute to the ornament, as well as to the accommodation of the town. The former is 1503 feet long, and 43 feet broad, stands on 75 piles, and cost 50,000 dollars. The latter is 3483 feet long, and 40 feet wide, stands on 180 piles, and cost 76,700 dollars. Besides these public buildings, there are seven free schools at Boston for the education of the citizens children.

The approach to Boston from the sea is singularly picturesque and beautiful. The town is built in an irregularly circular form round the harbour, which is studded with about 40 small islands, 15 of which afford excellent pasturage, and are frequented in summer by numerous parties of pleasure. The harbour itself, which is formed by Nahant Point on the north, and Point Alderton on the south, is so capacious, as to allow 500 vessels to ride at anchor in a tolerable depth of water. The entrance to the harbour, which is so narrow as scarcely to permit two ships to pass abreast, is defended by the fort of Castle William, erected upon Castle Island, and having 40 pieces of heavy artillery. On one of the islands, at the north entrance of the channel, is placed a lighthouse about 65 feet in height.

Prior to the late commercial decrees, which have proved so injurious to the trade of the United States, the trade of Boston was very considerable, as appears from the following statement:

	Vessels Cleared out.	Vessels Entered.
1748 . . .	500 . . .	430
1784 . . .	450 . . .	372
1794	567
1795	725

There are no fewer than 80 wharfs and quays in Boston. The long wharf, or Boston pier, stretches 1743 feet into the harbour. It is 104 feet broad, and at the extremity of it there is 17 feet of water at ebb tide.

The principal manufactures of Boston, are sail-cloth, cordage, cards for wool and cotton, playing cards, paper hangings, hats, plate, glass, tobacco, rum, loaf sugar, beer, and chocolate. There are in Boston 30 distilleries, 11 rope-walks, 8 sugar-houses, 2 breweries, and 3 banks. The principal societies are the American Academy of Arts and Sciences; the Marine Society; the Massachusetts Agricultural Society; the Massachusetts Historical Society; the Medical Society; the Humane Society; the Boston Library Society; and the Boston Mechanic As-

sociation; beside several religious and charitable institutions.

The town of Boston was settled from Charlestown in the year 1631. It received great damage from an earthquake on the 29th October 1727, and has since suffered severely from numerous fires, the houses being chiefly built of wood. In 1794, no fewer than 96 houses were consumed, and the loss sustained amounted to 209,861 dollars. Number of houses 2376. Population in 1790, 18,038; but since that time it has considerably increased. West Long. 70° 58' 53", North Lat. 42° 25' 13". See Morse's *American Geography*, p. 187. Morse's *American Gazetteer*. Wausey's *Journal*, London, 1796. A full account of the operations of Boston during the American war, and an excellent plan of the town, harbour, and environs of Boston, are to be found in Marshall's *Life of General Washington*, vol. ii. chap. iv. and vol. v. frontispiece. (π)

BOSWELL, JAMES, a celebrated literary character, was descended from an ancient and honourable family in Scotland. He was born at Edinburgh, October 29, 1740. His father, Alexander Boswell, was one of the judges in the supreme courts of Session and Justiciary, by the title of Lord Auchinleck, a man of a strong understanding, a sound scholar, a respectable and useful country gentleman, and an able and upright judge. His mother, Euphan Erskine, descended in the line of Alva from the house of Mar, was a woman of exemplary piety. He received the first rudiments of his education partly at home under private tuition, and partly at the school of Mr Mundell in Edinburgh. In his earliest years, he displayed that quickness of mind, vivacity of disposition, and taste for literature, which accompanied him throughout his life. He afterwards studied civil law in the universities of Edinburgh and Glasgow. This latter seminary was then, as it is now, very much resorted to by students from England, with several of whom Boswell became intimate, but with none so much as with Mr Temple, afterwards Vicar of St Glurias in Cornwall, who was a friend of Gray, and whose character of that poet has been adopted both by Dr Johnson and Mr Mason. This society confirmed in him a design, which he had early formed, of visiting England, and a predilection for English manners, which he has often been heard to say, was originally derived from a perusal of the lively representations in the Spectator. His first visit to London was in the year 1769, which afforded him the highest gratification. He happened, at his first entrance into the capital, to form an acquaintance with Derrick, an author by profession, who was afterwards master of the ceremonies, or king, (as it is termed), at Bath. Derrick was a man of some literature, but had hung loose about the world for some time, and was thus admirably qualified, by his lively talents and desultory habits, to introduce a stranger into all the varieties of a London life. The circumstances of this visit Boswell used often to detail with that felicity, for which he was always remarkable in narration, and exhibited so curious a picture of the scenes he had passed through, that his friend Dr Johnson advised him to commit it to paper and preserve it. Notwithstanding he was intended, by his education, for the bar, yet he was himself, at this period, earnestly bent upon obtaining a commission in the guards, and solicited Lord Auchinleck's acquiescence; but he return-

* Morse in his *Gazetteer*, makes it 97 streets; but in his *American Geography*, where the number of streets is expressed in words, he makes them 79. As it is more likely that there has been a transposition in the figures, than an error in the words, we have adopted the latter.

ed, by his desire, into Scotland, where he received a regular course of instruction in the law, and passed his trials as a civilian at Edinburgh. Though still anxious to pursue his original design, he at last relinquished it in compliance with his father's wishes, and consented to go to Utrecht in 1763, to hear the lectures of an eminent civilian, after which he had permission to make the tour of Europe. But before he quitted his native country, a circumstance took place, of no small importance to himself, and, as it afterwards appeared, of no small importance to the public. He obtained this year an introduction to Dr Johnson. He had long entertained the most enthusiastic admiration of that great man as a writer; and having learned that his powers in conversation were equal to his noblest productions, he was anxiously solicitous for his acquaintance. From hence we are to date a friendship which continued unabated to the last. Boswell, who saw every day, as his knowledge of Johnson increased, fresh evidences of the strength of his intellect and the goodness of his heart, regarded this venerable moralist with almost filial reverence; while Johnson, whose sagacious intuition into character, soon led him to perceive and appreciate justly the fertile talents, and truly amiable disposition of his young acquaintance, repaid his fervent affection with the most cordial attachment. Having continued one winter at Utrecht, during which time he visited several parts of the Netherlands, he commenced his projected travels. Passing from Utrecht into Germany, he pursued his route through Switzerland to Geneva, whence he crossed the Alps into Italy, having visited in his journey Voltaire at Ferney, and Rousseau in the wilds of Neuchâtel. But the most distinguished incident in his tour was, his spirited expedition into Corsica, then struggling against the tyranny of the Genoese. He adopted the feelings of those brave islanders with the most ardent enthusiasm, and commenced the most intimate friendship with their illustrious chief. He afterwards went to Paris, from whence he returned to Scotland in 1766, and soon after became an advocate at the Scotch bar. But, in the mean time, he was by no means forgetful of the interest of that gallant body of patriots whom he had left behind. He endeavoured to stimulate the statesmen of his own country to advocate their cause; and he had, on this occasion, the honour of a very interesting interview with Lord Chatham. One particular of this conversation which he has recorded, does equal honour to the liberality of the distinguished character by whom it was said, and to the great man of whom it was spoken. It may be said of Paoli, as the Cardinal de Retz said of the great Montrose, *C'est un des ces hommes qu'on ne trouve plus que dans les Vies de Plutarque*. The celebrated Douglas cause was at this time the subject of general discussion. Boswell, who had warmly adopted that opinion which was afterwards established by the decision of the first tribunal in Europe, justly thought that the great body of readers would scarcely endure the labour of extracting the real merits of the case from the voluminous mass of papers which had been printed on that question, and he therefore compressed them into a pamphlet, entitled, *The Essence of the Douglas Cause*, which had a considerable share in procuring for Mr Douglas the extensive popularity which a knowledge of his claims enabled him to obtain. In 1768, finding that the public were not a little anxious to learn the narration of him, "whom, (as Johnson expressed it,) a wise and noble curiosity had led where perhaps no native of this country ever was be-

fore," he published his *Account of Corsica, with Memoirs of General Paoli*. On the appearance of this work, he was again gratified by an encomium from Johnson's pen. "Your history is like other histories; but your journal is in a very high degree curious and delightful. * * * * You express images which operated strongly upon yourself, and you have impressed them with great force upon your readers. I know not whether I could name any narrative, by which curiosity is better excited, or better gratified." This book has been translated into the German, Dutch, Italian, and French languages; and his name by it has nearly acquired as much celebrity on the continent, as his admirable biographical work has procured for him at home.

In 1769, Mr Boswell was married to his cousin, Miss Margaret Montgomery. His union with this truly amiable and accomplished woman proved a source of felicity to him for many years; but he was doomed to suffer the affliction of losing her in June 1789. Dr Johnson had long formed the plan of visiting the Hebrides of Scotland in company with his friend, and in 1773, though at an advanced period of life, he put that plan in execution. They have both published an account of their journey. In 1782 lord Auchinleck died, and his son succeeded to the family estate in Ayrshire. The coalition ministry having been driven from power in 1783, for an attempt which Mr Boswell was convinced would have been subversive of the constitution, he published a pamphlet on the subject, entitled, *A Letter to the People of Scotland*, which produced considerable sensation, and for which he was complimented by Mr Pitt. But he was no party man; for, in the following year, a plan having been in agitation to reform the court of session, by the compendious mode of cutting off one-third of the number of the judges, Mr Boswell again embarked in politics, in opposition to the very ministry whom he had zealously supported before, when he thought them in the right, and, in *A Second Letter to the People of Scotland*, he remonstrated warmly against the measure, which was afterwards withdrawn. In 1784, he met with a severe affliction in the death of his illustrious friend Dr Johnson, who died on the 13th of December of that year. Mr Boswell, during his residence in Scotland, had no inconsiderable practice at the bar, and enjoyed the intimate acquaintance of the most celebrated among his countrymen, of lord Kaimes, lord Hailes, Dr Robertson, Dr Blair, and Mr Beattie, besides a numerous circle of other persons, distinguished for their rank, talents, and virtues; but his love for London, and its wide and varied scene of life imbibed in his youth, and which gained strength as he grew older, determined him at last to settle with his family in the metropolis, which he did in 1786, having a short time before been called to the English bar. In 1785, he published his *Journal of a Tour to the Hebrides*, which not only forms a striking part of his delineation of Johnson, but is replete with interesting information on various topics. There has no where appeared so lively or so affecting an account of the difficulties and escape of the grandson of James II. after the battle of Culloden. From this time he was for some years most assiduously employed in preparing his great biographical work for the press. At last his *Life of Dr Johnson* appeared in 1790, in 2 vols. 4to. Of this work the public expectation was high, and it was amply gratified. Never before had the world seen so full, so faithful, and so correct a representation of an eminent man. Those who had been unacquainted with Johnson

were now introduced into his society, and enjoyed "the feast of reason" as much as if they had conversed with him for years. Those who had known him found their knowledge so agreeably renovated, and so enlarged, that many of them confessed, that they had a more vivid idea of Johnson's character and colloquial powers from Mr Boswell's narrative, than their own experience, even in actual intercourse with him, could have supplied. This work, however, did not escape criticism: Some objected to the minuteness of the relation, and the introduction of petty details; but it should be recollected, that circumstances which, separately taken, are of little moment, when united together go to constitute a full and lively resemblance, instead of that meagre outline which biographers in general are content to display. Others maintained, that Johnson's virtues were such, that no mention should have been made of his failings; but to this it may be observed, that the mode they recommend would have been contrary to that strict regard for truth which Johnson himself always inculcated in works of this nature; and, secondly, that this plan would have defeated its own purpose. The world was already in possession of the writings of sir John Hawkins and Mrs Piozzi. Had Mr Boswell confined himself to the exemplification of his great friend's virtues alone, the unfair and false exaggerations of the others would have been considered as the real reverse of the picture. He did better: By a candid, unvarnished exhibition of the whole truth, he clearly proved that his faults, when compared with his excellencies, were as dust in the balance. Others there were who, unable to deny the merit of the work, attempted, with feeble effect, to tear the laurels from the brow of the author. It required no great power of mind, they observed, to record the brilliant sayings of others. Nothing can be more ignorant than this remark. There is no faculty more rare. "Few people," said a celebrated wit, "can *carry* a bon mot: It cannot then be easy to carry as many as will fill two quarto volumes." But, in fact, it is a false representation of the *Life of Johnson*, to describe it as merely a collection of good sayings. Valuable as it is in that respect, it is far from being the whole of its merit. It contains an exquisite delineation of character, conveyed throughout with dramatic vivacity, and proves the writer, as has been truly observed, to have had a picturesque imagination, and a turn for poetry as well as humour. It is remarkable that, notwithstanding his enthusiastic admiration of Johnson, he is free from all attempt at imitation, and has never transposed "the long majestic march" of the great moralist's language into his own style, which, though

frequently enlivened by a happy vein of imagery, is uniformly simple and unaffected.

On the publication of this work, he was gratified with the most liberal applause by his most distinguished contemporaries. Nor were their sentiments in its favour expressed to himself alone: Mr Burke, in a conversation with sir James Mackintosh, declared, that Boswell's *Life* would do more honour to Johnson than all his works put together. Such an encomium from such a man will much more than counterbalance all the willing sneers with which dulness, spleen, or malice, have assailed him. From this time till his death, we have nothing memorable to record. In 1795, he was suddenly seized with an ague. The confinement which this disorder occasioned brought on a painful complaint to which he was subject, and he died at his house in London, on the 19th of June.

As a writer, his works must speak for him; as a man, his character will be always remembered by those who knew him with affectionate regret. He has been described by others, and has even described himself, as being vain; but his vanity was of that playful kind, and so remote from all wish to depress others, that no one, whose temper was not sour indeed, could possibly have been offended with it. He had his foibles; who has them not? His fondness for social conviviality sometimes led him into excess, but his principles were always untainted. In politics, he was at once a steady royalist and an ardent friend of genuine liberty. In religion, he was from thorough conviction a member of the English church; but intolerance, or enmity towards those who differed from him, would have been totally inconsistent with his mild disposition. "I can drink, I can laugh, I can converse," as he tells us, "in perfect good humour, with Whigs, with Republicans, with Dissenters, with Independents, with Quakers, with Moravians, with Jews. They can do me no harm: my mind is made up: my principles are fixed: But I would vote with Tories, and pray with a Dean and Chapter." Such was his good humour, that Mr Burke remarked, he had so much of it naturally that it was scarcely a virtue. His lively and fertile mind, and his rich fund of anecdote, made him an inimitable companion. The old, the young, the grave, and the gay, were all equally fascinated and borne away by the irresistible hilarity of his manner. His heart was harmless, and his benevolence active. Let us add to him that praise, without which all other praise must be wretchedly imperfect,—he lived and died a sincere and humble Christian. (F)

BOSWORTHII, BATTLE OF. See BRITAIN, *Ind. 2*

GENERAL EXPLANATION
 OF THE
PLATES BELONGING TO VOLUME THIRD,
 OF THE
AMERICAN EDITION
 OF THE
NEW EDINBURGH ENCYCLOPÆDIA.

PLATE XLIX.

- Fig. 1. For explaining the method of measuring the Attraction of Mountains.
 Fig. 2. Machine employed by Mr Cavendish, in his curious experiments on the attraction of Leaden Balls.
 Fig. 3.—Fig. 16. Diagrams for illustrating the article **ATTRACTION.**

PLATE L.

Contains Diagrams for illustrating Professor Playfair's investigations respecting the Solid of greatest Attraction.

PLATE LI.

- Fig. 1. A perspective view of Mr Troughton's Balance, for nice philosophical experiments.
 Fig. 2. Section of the Beam of Mr Troughton's Balance.
 Fig. 3. Apparatus employed when the Balance is used for hydrostatical purposes.
 Fig. 4. A perspective view of Mr Troughton's Assay Balance.

PLATE LII.

- Fig. 1. A View of a Balance constructed by Messrs Miller and Adie of Edinburgh, and in the possession of Mr Jardine.
 Fig. 2. Section of the Ends of the Beam.
 Fig. 3. Plan of the Apparatus or Press used in the manufacture of Imitation Bandana Handkerchiefs.
 Fig. 4. Section of this Apparatus, representing also a new method suggested by Mr John Duncan of Glasgow, for pressing, by water, the Handkerchiefs between BB and CC.

PLATE LIII.

- Fig. 1. View of a Barley Mill of the most approved construction.
 Fig. 2. For explaining the Torricellian Vacuum.

- Fig. 3. Representation of the common Chamber Barometer.
 Fig. 4. View of the extremity of the Barometer Tube.
 Fig. 5. View of Descartes' Barometer.
 Fig. 6. View of Huygens' Barometer.
 Fig. 7. View of Dr Hooke's Barometer.
 Fig. 8. View of the Inclined or Diagonal Barometer.
 Fig. 9. View of the Rectangular Barometer.
 Fig. 10. View of a Barometer with a Lever.
 Fig. 11. View of Rowning's Barometer.
 Fig. 12. View of Mr Keith's Self-Registering Barometer.

PLATE LIV.

- Fig. 1. View of the upper part of Mr Troughton's Portable Barometer.
 Fig. 2. View of the lower part of Mr Troughton's Portable Barometer.
 Fig. 3. Perspective view of Mr Troughton's Portable Barometer, when mounted on its stand or staff.
 Fig. 4. View of the whole instrument when packed up within its stand.
 Fig. 5. View of the structure of the Staff Head upon which the Barometer is suspended.
 Fig. 6. View of a Barometer constructed by Messrs Miller and Adie of Edinburgh.
 Fig. 7. Perspective view of Mr Troughton's Marine Barometer.
 Fig. 8. View of the Gimbals upon which the Marine Barometer is suspended.
 Fig. 9. Section of the lower part of the Marine Barometer.
 Fig. 10. Perspective view of the upper part of the Marine Barometer.
 Fig. 11. View of the Wheel Barometer invented by Dr Hooke.

PLATE LV.

- Fig. 1, 2, 3. Represent the Dash Wheel, used for washing in the operation of Bleaching.

- Fig. 4. End view of the Squeezers, as constructed by Mr Parkinson of Manchester.
 Fig. 5. Front view of the Squeezers.
 Fig. 6. Represents a side view of the wash Stocks which are used in Bleaching, to free the goods from the loose stuff which may be attached to them.
 Fig. 7. Represents an end view of the same wash Stocks.

PLATE LVI.

- Fig. 1. No 1st and 2d represent Sections of Stone Boilers for the recovery of waste alkali.
 Fig. 2, 3. View of a Bucking Apparatus used in Bleaching, and invented by Mr John Lourie, of Glasgow.
 Fig. 4. View of an Apparatus for making the Oxymuriatic Acid, invented by Mr Peter Fisher of Rutherglen.

PLATE LVII.

- Fig. 1, 2. Views of a *Snatch Block*, which is used for heavy purchases.
 Fig. 3. View of the *Long Tackle block*.
 Fig. 4. Perspective View of the *Boring Machine*, employed for boring the hole for the centre pins of blocks, and a hole for the commencement of the mortise which contains the sheave.
 Fig. 5. Perspective View of the *Corner Saw* for cutting off the corner of the solid parallelepipedons after they have been bored.

PLATE LVIII.

- Fig. 1. View of the *Clue-line Block*, invented by Mr Brunel.
 Fig. 2. View of the *Shoulder Block*.
 Fig. 3. View of the *Spring Block*, invented by Mr Hopkinson of Philadelphia, for assisting a vessel in sailing, by increasing the acting spring of her rigging.
 Fig. 4. Perspective View of the *Mortising Machine*, for mortising out the cavities for the reception of the sheaves of the blocks.

PLATE LIX.

Perspective View of the *Shaping Engine*, for forming the outside of the blocks to their proper figure.

PLATE LX.

- Fig. 1. Perspective View of the *Scoring Engine*, for forming a groove round the longest diameter of the block, for the reception of the strap.
 Fig. 2. Perspective View of the *Crown Saw*, for cutting

out a circular piece of wood, and at the same time forming a hole exactly in the centre of it.

PLATE LXI.

- Fig. 1. Perspective View of the *Coaking Engine*, for forming a cavity in the form of three small semicircles in the centre of the sheave, for the reception of the coak or metal bush.
 Fig. 2. Perspective View of the *Face turning Lathe*, for turning perfectly flat the faces of the metal coak and of the block.

PLATE LXII.

- Fig. 1. View of Cronstadt's Blow-pipe.
 Fig. 2. Blow-pipe said to be invented by Dr Black.
 Fig. 3. Newly invented Blow-pipe.
 Fig. 4. Dr Wollaston's portable Blow-pipe.
 Fig. 5. Blow-pipe with a cylindrical Box and moveable Jct.
 Fig. 6. View of the Platina Spoon for holding the object.
 Fig. 7. Perspective View of Professor Pictet's Alcohol Blow-pipe.
 Fig. 8. Perspective View of Mr Benjamin Hooke's Alcohol Blow-pipe.
 Fig. 9. New Blow-pipe, invented by the Author of the Article, and constructed upon the principle of the blowing engine.
 Fig. 10. View of the Nose Pipes used in the experiments made at the London Philosophical Society, with blow-pipes acting with oxygen gas.
 Fig. 11, 12, 13, 14. Hare's Blow-pipe

PLATE LXIII.

- Fig. 1. Perspective View of the Blowing Engine Cylinder and Water Regulator, for projecting, with great force, a continued stream of air into furnaces, for the purpose of increasing the combustion.
 Fig. 2. View of the Valves.

PLATE LXIV.

- Fig. 1. Elevation of a Mill for putting in motion two Boring Engines.
 Fig. 2. A longitudinal Section of the Cutters employed in boring.
 Fig. 3. A traverse Section of the Cutter.
 Fig. 4. View of the Cutter fixed upon the Axis.
 Fig. 5. A perspective View of the Boring Machine in the act of boring out a cylinder for a steam engine.

PLATE LXV.

- Fig. 1. to 21. Diagrams for illustrating Boscovich's Theory of Natural Philosophy.
